Miss Sally Johnson, R.N., chairman of the Legislative Committee of the Massachusetts State Nurses Association, discussed pending legislation in which nurses are interested.

The May Meeting schedules Miss Ethel M. Johnson, assistant commis-

sioner of labor and industries to speak on "How Massachusetts Protects Working Women and Children."

Massachusetts Holds Health Conference

Through the cooperation of the Massachusetts Central Health Council, sixteen state-wide agencies, joined forces in a health conference held at Springfield, April 26 to 28.

The practical value of such a conference is readily seen in the correlation of such problems as the relation of infantile paralysis to the public health question, discussed by no less an authority than Dr. Robert W. Lovett; social hygiene, by Dr. Enos H. Bigelow; mental hygiene, by Dr. George K. Pratt; cooperation of all agencies, by Dr. Donald B. Armstrong; community health, rural health, school hygiene, and every phase of individual effort that would be made more effectual through finding its proper place in a concerted program came in for due consideration and expert handling.

The most significant part of the conference was the fact that every agency, voluntary and state, lay and professional, practical and technical, was represented.

Hygiene or Therapeutics?

WE ARE indebted to *Practical Medicine and Surgery* for the following excerpt from "What's Doing in Colorado."

While traveling in the Pacific Coast states recently Herschel H. Hall was taken violently ill with an attack of acute indigestion.

Hearing there was a Chinese doctor in the town, who was highly regarded by the citizens of the locality, Mr. Hall sent for him.

The physician came, felt of the sick man's pulse, inquired briefly as to his suffering and then entered upon the following questionnaire:

"You smokee sli-ga-let."

"Oh, Yes."

"Cigar, too?"

"Yes."

"Pipe maybe, eh?"

"Sometimes."

"You take li'l dlink sometimes—maybe col' pop, col' soda, col' milk shake, col' linger beer, liey-col' lemonade, col' slider, maybe some hot tlea, hot coffee, hot chocolate, lots of sugar and cleam?"

"Sure thing!"

"You eattee fast?"

"I got to, doctor—always in a hurry—lots to do, you know."

"You eattee hot biscuit?"

"You bet!"

"You eattee fly ham, fly bacon, fly eggs, hot clakes, lots molass?"

"I'll say I do!"

"You eattee gleasy stuff—some fly some roast, some boil, some stew, some blake—you mix em' all uppee same time, eh? Maybe some jam and gleasy glavy sametime, eh?"

"Yes, everything goes with me."

"You eattee pie?"

"Pie? Pie is my middle name at mealtime, doctor."

"You eattee some pickle, some cheese, some nut, some nice lich clake, some lice cleam—you mixee all uppee inside same time, eh?"

"Yes, sir—that was the way I was taught to eat at boarding school."

"You dlinke lice water same time?"

"Of course."

"You chewee up wood toothpickce fine, eh, at finish?"

"Usually do—sometimes I have to use a match."

"Good nightee! I can no curee damn fool!"

Passing Fads in the Manufacture of Dentifrices

Not a Medicated Dentifrice. Years ago Colgate & Company refused to meet artificial demands for a highly medicated dentifrice. They followed scientific dentists in the contention that strong drugs are harmful to the mucous membrane of the mouth. Such drugs should not be used in a dentifrice except in the treatment of pathological conditions, and then only under the advice of a dental practitioner.

Not an Acid Dentifrice. Once more Colgate & Company's stand is with the scientific members of the medical and dental professions who refuse to use an acid tooth paste. Those doctors recommend to their patients a dentifrice with high cleansing qualities, pleasant to taste, containing a thorough non-gritty cleanser.

Colgate's Dental Powder holds a high position among those of the dental profession who prefer a dentifrice in powder form. As with Ribbon Dental Cream, it is based on the same fine precipitated chalk and pure soap.

A generous supply of samples will be sent postpaid to professional friends upon request.

Truth in Advertising Implies
Honesty in Manufacture

Middle West Society of Physical Education

Famous educators, world champion athletes, student health experts, and school physical directors—each with a somewhat different conception of what should be the physical education program in schools—conferred together on the occasion of the tenth annual meeting of the Middle West Society of Physical Education at the University of Chicago April 19 to 21. An attendance of something over eight hundred people attests the universal interest in the subject.

The subject of physical education in general, and the status of the physical educational teacher in particular, were particularly well summarized in a sensible and stimulating address by Professor James Weber Linn of the University of Chicago. The advantages of physical education over other means of education, said Professor Linn, are very great. First, a very definite objective is possible—the development of perfectly sound, perfectly controlled bodies. Where the average teacher has only the faintest idea of what he is trying to do, the teacher in physical education knows exactly what he wants to do, and how to do it.

Notwithstanding the extraordinarily definite need for health and sport-manship, teachers of physical education are subject to a remarkable lack of prestige. Famous men in physical education we have not, said Professor Linn; physical education is a pursuit, not a profession. The demand is terrific; anybody can get a "job" as physical educator. When physical educators themselves impose scholastic background, standard practice, and appreciate as a group the vital relationships of their calling it will be no less professional than economics, medicine, and other sciences.

Necessarily the demonstrations were the nature of "stunts" by picked groups rather than typical examples of average results of mass methods, but they were interesting and illuminative.

The problems of athletics found their best discussion in one of the section meetings by Professor C. W. Savage of Oberlin College, and means of selling physical education to the public, and of appreciating physical educational health values were expressed in terms of psychology of advertising by Harry N. Tolles, president of the Sheldon Correspondence School, Chicago.

Dr. J. Anna Norris, University of Minnesota, was elected president for

the ensuing year and Floyd A. Rowe, Lansing, Mich., re-elected secretary.

N. Y. Public Health Courses Attract High Type Nurses

Analysis of educational qualifications of the 250 nurses who have enrolled for the correspondence course in public health nursing recently opened by Columbia University and Bellevue Medical College in cooperation with the New York state department of health shows that the general educational level among the nurses of New York state is higher than supposed, the department says: Nearly 40 per cent of these applicants have had a four years' course in high school; more than 4 per cent have had at least two years in college.

More than 65 per cent of this group are found to be graduates of training schools connected with hospitals of more than 100 beds and giving a training of not less than two years. Less than 4 per cent have had no hospital training. More than 30 per cent are graduates of training schools giving at least two years' practice, connected with smaller hospitals of less than 100 beds.

The plan of the correspondence course is to introduce the nurse to the whole field of public health in such a way that she will understand the pertinent features of a state-wide public health program.

An Outbreak of Cheese-Poisoning Studied

Outbreaks of illness following the consumption of cheese are of great rarity. An epidemic attributable to this cause was recorded in London in 1901, but the majority of outbreaks recorded have been in America. The main features of cheese poisoning resemble those of poisoning from other infected foods, but one or two minor points of difference are brought out by Dr. H. M. Cameron Macaulay in *The Lancet* in his study of an outbreak of cheese poisoning at Dover in July, 1922.

Cameron does not find evidence of a single fatal case in any outbreak where the circumstances incriminating the cheese have been at all conclusive, whereas in other food-poisoning epidemics the case mortality is in the neighborhood of 1.5 per cent. Another point of difference is that the period of incubation appears to be shorter in cheese poisoning, and the usual food-poisoning organisms are hardly ever found in epidemics due to cheese.

The nature of cheese as a food affords an explanation for these differences. Cheese occupies the unique position of being practically the only article of food prepared many weeks or months before it is intended for consumption and not subjected to any process of preservation during that period. Moreover, bacterial action, so far from being inhibited, is encouraged along definite channels in order to bring about ripening.

This very fact makes it unlikely that in the event of a pathogenic organism being introduced in process of manufacture would remain alive at the time of consumption, the growth of the saprophytic bacteria and molds associated with the ripening process being unfavorable to the growth of the usual pathogenic organisms.

It is usual, therefore, in the rare instances when food poisoning has been attributed to cheese to find the Gaertner organisms present, a group almost invariably associated with an extremely stable toxin, capable of withstanding a temperature of 100° C. for five minutes. Care was taken to exclude the food handlers as carriers. Cheese poisoning, therefore, Dr. Macaulay considers to be a pure intoxication and infection with Gaertner organisms. This theory is in need of confirmation by further study.

National Museum of Engineering and Industry

The Society of Industrial Engineers is responsible for the activities of a committee which is at work formulating a plan or the establishment of a national museum of engineering and industry. A central institution will be provided and branches in different sections of the country will be established as conditions may require. The preliminary studies on the project are under the direction of H. F. J. Porter, 29 West 39th Street, New York City.

Aeronautical Safety Code Now Being Developed

The work now under way in the development of an aeronautical safety code is discussed in *Aviation*. In its complete form it will represent the first edition of the American Aeronautical Safety code. When the sectional committee in charge of its preparation gives it permanent form, it will be submitted to the Bureau of Standards and to the Society of Automotive Engineers before it will go on record as an achievement in a new field of industrial hygiene.

Comfortable New Shoes
for Pleasant Spring Days

when the whole world stretches out before you like a green carpet.

HAPPY Spring days, full of warmth and sunshine. On such days wouldn't you like to feel "foot-free," refreshing your spirits as you walk with springy step under soft, bright skies?

foot and supports it, leaving your foot free to strengthen through exercise. The natural lines of the shoe allow ample toe room, and the low, medium, or Cuban heel gives your body a healthful graceful poise.

It is unnecessary to pamper your feet in old shoes at this glorious time of year. In new Cantilever Shoes you walk with foot freedom and real comfort.

Cantilevers give you unusual comfort because they are built not only to fit the foot, but to act with it. Natural movement is not restricted, because the Cantilever has a flexible shank which curves up to follow the arch of your

Cantilevers are made in soft, light-weight leathers. Their attractive styles harmonize with Spring costumes. You find good looks as well as comfort in Cantilevers.

Except in New York and Chicago, only one store in each town sells Cantilevers. If a dealer near you is not listed at left, write the manufacturers, Morse & Burt Co., 15 Carlton Ave., Brooklyn, N. Y., for name and address of a nearby dealer, and a new booklet about feet and shoes.

End read by Women's College, Women's Clubs, Public Health Authorities, Physicians, Opticians, Directors of Physical Education, Editors, Stage Celebrities and prominent men everywhere

The Health Situation in California

The recently issued report of the California State Board of Health, covering the period from July, 1920, to July, 1922, is in the main a cheering document, with numerous statistics showing control of disease and reduction of mortality.

Chief among accomplishments are the reduction of tuberculosis and typhoid, and the lowering of the infant mortality rate. In spite of the persistent migration of tuberculous patients to California, the death rate from the disease has been reduced from 216 per hundred thousand in 1906 to 150 per hundred thousand in 1921. Typhoid has become so rare that in some sections of the state a considerable number of practitioners have never been afforded the opportunity of seeing cases. The infant mortality rate has decreased from 160.0 in 1906 to 66.8 in 1921.

The causes to which the improvements are to be attributed are of course numerous and complex. Of primary importance was the establishment of new public health machinery, and increased interest in community health.

When the complexity of California's health problem is considered, great credit is due the physicians for their achievement. The tremendous flow of tuberculous persons into the state, typhus fever ever present on the southern border, and the potential danger in other dangerous diseases from Oriental sources, render the situation unique, to be met with expedients unknown to the scientists of other states.

James A. Tobey to Administer Health Council

James A. Tobey, Washington representative of the National Health Council, has been appointed administrative secretary of the Council with offices in New York City. He succeeds Walter Clarke.

Mr. Tobey is a graduate in sanitary engineering and public health of the Massachusetts Institute of Technology, and of law from the Washington Law School. He has served as health officer of Summit and West Orange, N. J., as representative of the New Jersey State Department of Health, as scientific assistant with the United States Public Health Service, and, during the war, as a first lieutenant in the U. S. Army Sanitary Corps. Mr. Tobey will assume his new duties June 1.

Maternity and Infant Care in Berlin and Stockholm

A picture of the outstanding resources for "Public Maternity and Infant Care in Berlin and Stockholm" has been recently prepared by Elizabeth Phinney Hunt of Bryn Mawr College at the University of Stockholm.

"In Berlin, when an illegitimate infant is born the local city registrars are required to report the birth to the Division of Public Guardianship, which thereupon immediately appoints a public guardian for the child. This guardian supervises the development of the child until it is twenty-one years of age. There are twenty-four public guardians in Berlin, each of whom has in his or her care about one thousand children. It is furthermore the duty of the public guardian to see that the father makes the payment to the mother of the child, that is required by law."

Reference is made to Guinchard who has stated that "in the years 1901-10, 33.6 per cent of the children born alive in Stockholm were born out of wedlock. The 1920 Statistical Yearbook for the city of Stockholm gives the figures for total living born and total illegitimate children. The approximately percentage of illegitimacy indicated by these are: 1902, 33 per cent; 1907, 34 per cent; 1912, 37 per cent; 1917, 30 per cent; 1919, 27 per cent.

Industrial Dental Clinics in Pennsylvania

The close relationship between certain industrial diseases, notably lead poisoning and diseased teeth, was one of the moving causes for the survey made by the Division of Hygiene of the Pennsylvania Department of Labor and Industry to determine the extent of dental service for employees.

Replies were received from fifty-nine industries. Thirty-three plants employing 209,743 persons reported that the total number of employees taking advantage of dental service were 125,222, or 59.7 per cent. Fifty-nine plants employed dentists, forty for full time.

It was found that seventy-five nurses, twenty-six attendants, and twenty-six clerks were employed in all plants for dental service.

The average cost of original dispensary equipment to the fifty-three firms replying to this question was \$1,958.03; the least cost of equipment in one plant was \$328.28; the greatest cost was \$8,000; while the total cost in all plants was \$103,775.46. Cost of operating the dispensary per year per patient was: Average cost, \$3.38; least cost, 30 cents; greatest cost \$27.19.

Fifty-five of the fifty-six firms replying stated that they considered the operation of an industrial dental dispensary a success; one considered it only partially successful.

Copenhagen Serum Institute Laboratory

Examine Your Patients' Feet for Structural Weaknesses

Weak or fallen arches or flatfoot are often the direct cause of many bodily complaints such as fatigue, nervousness, pain in legs, sciatica, painful heel, cramped toes and rheumatic symptoms. Mechanical treatment is indicated along with properly fitted shoes.

Dr Scholl's *Corrective Foot Appliances*

are especially designed on anatomical and approved orthopedic principles to relieve the cause of the ligamentous strain and correct the abnormal posture. Worn inside the shoes, are comfortable to wear and easily adjustable to meet all conditions as presented to the physician.

Sold at Shoe Stores

Better shoe stores in every locality carry the full line of Dr. Scholl's Corrective Foot Appliances and have also been instructed in how to properly fit them. Write us for the name and address of the dealer nearest you, Doctor, and let us

tell you more about mechanical orthopedics of the foot, which subject is attracting so much attention from the medical profession at this time.

Dangers in the Use of Radiant Gas Heaters

Warning that improper combustion of natural-gas in heating appliances in common use may liberate carbon monoxid, is given by the Bureau of Mines, as the result of studies at its Pittsburgh experiment station.

Quantities of carbon monoxid as low as 0.2 per cent may produce death in a short time. For healthy atmospheric conditions in the home, in which the occupants are continuously exposed, carbon monoxid should not be present in amount greater than 0.01 per cent.

As a result of its investigations, the Bureau offers the following suggestions regarding the operation of radiant-fire heaters burning natural gas to prevent liberation of carbon monoxid:

(1) Do not operate a radiant-fire heater so that the radiants glow more than three-quarters the distance from bottom to top. When this rate is exceeded, carbon monoxide is liberated in more or less dangerous quantities.

(2) For all gas flows in which the radiants glow from one-quarter or more of the distance from bottom to top, the adjustment should be made from the needle-valve rather than the gas-cock. Open the gas-cock as far as possible, then close the needle-valve to give the desired gas flow or flame length. By adjusting the gas flow from the needle-valve with gas-cock wide open, the highest possible orifice pressure is obtained, which, as shown, raises the air-gas ratio, increases the completeness of combustion, and diminishes the liberation of carbon monoxid for a given gas consumption.

(3) An over-size orifice should be used with caution, and manufacturers should discourage the use of such an orifice for low gas pressure. A heater is properly made for a given size orifice, so that a minimum quantity of carbon monoxid is produced. When the standard orifice is replaced with an over-size orifice, the air-fuel ratio is lowered, the completeness of combustion is reduced, and liberation of carbon monoxid is increased for a given gas consumption. The greatest danger is that the operator may not change back to the standard orifice when the gas pressure becomes normal, and the heater will then be operated at too high a rate for good combustion.

(4) Since, when burning artificial gas, a larger size orifice is needed than for natural gas, dangers may arise when a heater which has been

used in a region where artificial gas was supplied, on moving to a natural gas region is used without changing to a smaller orifice. In such a case the heater is operated at two to three times its rated capacity, with the liberation of dangerous quantities of carbon monoxid. Two deaths in the Pittsburgh district during December, 1922, were caused by operating a heater (not a radiant type) with an orifice intended for artificial gas on a natural gas heater.

(5) Manufacturers should stamp on each heater sold (this does not apply to yellow-flame heaters), in some conspicuous place where not easily removed, what kind of gas the heater is intended for, such as, "For Natural Gas Only," or "For Artificial Gas Only;" and the orifices should be locked and accompanied by instructions not to change without consulting the local gas company.

(6) Heaters should be of sufficient size to heat a given room at normal rating, rather than of a smaller size and operated at excessive rates. If a radiant heater has an adjustable primary air inlet, to be sure this is as wide open as possible, or better yet remove it and throw it away. (Six deaths in Ohio during

December, 1922, were largely due to having the primary air inlet closed.) For safety's sake buy an over-size heater rather than an over-size orifice. When a period of low gas pressure arises, the over-size heater will then be large enough to furnish sufficient heat without changing to a larger orifice, with its inherent dangers of liberation of carbon monoxid.

(7) Flues on radiant heaters are always desirable. Heaters operated at excessive gas flows, or used with over-size orifices or poorly constructed, giving low air-fuel ratios at the burner ports, should be attached to flues.

(8) Never sleep in a room in which a flueless heater is burning without having at least one window wide open to supply adequate ventilation. This one precaution would have prevented many deaths during the past few months.

June 26, 27, and 28 have been selected by Dr. Herman M. Biggs, State Commissioner of Health as the dates for the Annual State Conference of Health Officers and Public Health Nurses. The Conference will be held at the Grand Union Hotel, Saratoga Springs.

Health Statistics Evaluated

THE Report of the Connecticut State Department of Health for the two years ending June 30, 1922, states that "Unfortunately the balance sheet of a health department showing lives saved and sickness reduced does not alone impress all with the fact that money spent for health work produces greater return for a dollar invested than any other public expenditure."

Connecticut spent approximately \$2,000,000 during 1921 for the promotion of public health. As a result the lives of 4,700 people were saved or prolonged and many thousand cases of sickness were prevented. "Applying the methods of calculation promulgated by the National Conservation Commission, it is found that the lessened deaths and sickness represent a saving to the people of the state of over \$10,000,000 for the year 1921, as compared with the losses sustained five years ago. The net profit on the \$2,000,000 expenditure was \$8,000,000."

The report further states that if the public sentiment will sustain the effort with necessary appropriations it is possible to eliminate a calculated

Health work usually finds expression in terms of dollars or time expended. Connecticut has made a graph which sets forth the death rates and per capita expenditure.

preventable loss of \$32,000,000 still remaining.

“It stimulates peristalsis —and at the same time softens the fecal masses” . . .

That is the conclusion of a noted investigator who recently concluded a series of tests on the effects of Fleischmann's Yeast in constipation.

Authorities have suggested that the increasing prevalence of constipation is due largely to the deficient bulk of many concentrated, artificial modern diets. Where careful dietary regulation proves ineffective, Fleischmann's Yeast offers a valuable supplement.

Recent experiments show that fresh yeast, in quantity of two to three cakes per day, produces by its action a definite increase both in the bulk of the feces, and in their moisture content.

Fleischmann's Yeast is not habit-forming, and may be used *without* the difficulties attendant upon the use of cathartics and “laxatives.” Physicians and hospitals in many

parts of the country are now prescribing it with gratifying results.

Not only does it assist regular intestinal activity, but its vitamin content is highly beneficial, and experiments have shown that it also helps to produce a definite leucocytosis.

Best results are obtained by eating one cake half an hour before each meal, or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk or fruit juices.

A new authoritative book: written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry and therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing The Fleischmann Company, Dep. Y-19, 701 Washington Street, New York, N. Y.

FROM THE FIELD

The population of the continental United States on January 1, 1923, was approximately 110,100,000, according to an estimate given out by the National Bureau of Economic Research. This showed an estimated gain of 4,500,000 since 1920.

This gain in population has been brought about partly by increase in immigration, reinforced by a reduction in the death rate. At the present rate of growth the population at the 1930 census will reach 120,000,000.

Approximately \$150,000 has been subscribed by the meat packers to begin actual development of the "institute plan," according to an announcement by Thomas E. Wilson, chairman of the Plan Commission of the Institute of American Meat Packers. The institute plan provides for the ultimate development at Chicago of a combined educational institution, research institute, trade association and industrial museum. The institution will be national in character and will serve the entire packing industry. One of the first steps will be a series of lectures at the University of Chicago, giving a perspective survey of the meat industry.

The National Health Council has prepared and published a comprehensive list of educational motion pictures on health subjects. Over three hundred titles are included in the list which gives in addition to the title the number of reels or the length; the name of the distributor, the rental or sale price; and a brief note about the subject matter of the film. The film list will be sent to any person or institution interested in motion pictures on health subjects but it is intended especially for public health workers connected with official and voluntary agencies. A charge of \$0.35 per copy is made for the list, which may be secured by addressing the National Health Council, 370 Seventh Avenue, New York City.

New York hospitals treat four times as many patients in their dispensaries as they do in their wards, yet the financial support given to the dispensaries is entirely disproportionate to the extent of the service rendered, according to a special committee, representing the Associated Out-Patient Clinics, which has recently com-

pleted a report on the financial problems of dispensaries.

A comprehensive report on the suicides of 1922 in the United States has been issued by Dr. Harry M. Warren, president of the Save-a-Life League. Of the twelve thousand persons who committed suicide, four thousand were women and nine hundred children. The list includes wealthy, prominent and highly educated persons; there were 38 college students, 50 college professors and school teachers, 19 preachers, 52 judges and lawyers, 84 physicians and 100 captains of industry. Seventy-nine were millionaires. The most appalling statistics were those on child suicide, the rate of which has doubled since 1919.

More than three-fourths of the countries from which immigrants are entering the United States already have reached their full limit of the number they may send in the fiscal year ending with June, and it is estimated that the Spring inflow from the few countries which have not filled their quotas will bring the arrivals in the year up to nearly or quite the 358,000 permitted under the law of May 19, 1921. The principal countries represented by the 14,000,000 persons of foreign birth living in the United States in 1920 were stated in numerical order, Germany 1,686,000, Italy 1,610,000, Russia 1,400,000, Canada 1,196,000, Poland 1,140,000, Ireland 1,037,000, England 813,000, Scotland 253,000. The Scandinavian States as a group are represented by slightly more than 1,000,000 persons. Sweden having more than one-half of this total. The number of natives of France, Netherlands, Belgium and Switzerland is comparatively small, those of France being but 120,000, exclusive of Alsace-Lorraine, Netherlands 132,000 and Belgium 62,000.

According to the records of the New York Lying-In Hospital, during the last ten years, 754 practicing physicians from 105 municipalities in New York state have received postgraduate maternity training at that institution. Of this number 30 are from villages having a population of less than 1,000. The records also show that during the above named period,

from every state in the Union has come at least one practicing physician for postgraduate work; 3 have come from Alaska; 100 from Canada, and 47 from 18 foreign countries.

More than \$9,333,000 was spent on public recreation last year by cities and towns reporting to the Playground and Recreation Association of America, it has been announced. For this purpose \$155,180 was voted in bond issues, and more than \$600,000 worth of land donated by private citizens, while 378 cities showed municipal support, entire or partial.

The Court of Appeals of the District of Columbia has handed down an opinion in a case which was brought by several residents of the District of Columbia against the Commissioners of the District to prevent the latter from erecting a school for tuberculous children on a site of ground north of Upshur Street in the City of Washington. On this site there is already a municipal hospital and a junior high school. Congress had appropriated a sum of money for the erection of a school for tuberculous pupils although it had not stated in the act just where this school should be placed. The Court of Appeals examined all of the Acts of Congress since 1900 referring to this matter but failed to find any authorization for the erection of the "building for the care of tuberculous pupils" on this particular location. Having considered the matter purely from the standpoint of the law, the Court accordingly dismisses the appeal of the Commissioners. This case, holding up the erection of a much needed school for tuberculous children in the District of Columbia, shows the necessity for getting specific and unquestionable legislation for public health items and sociological matters. Through a legal technicality, a matter of great benefit to the prevention of tuberculosis has been handicapped and postponed for some time.

Four delegates of the Council of Jewish Women have been appointed to complete investigations and surveys in the principal port cities of Europe, on employment opportunities and housing conditions affecting detained emigrants and refugees. They will observe the work that is being done by the Foreign Unit of the Council of Jewish Women, and will then proceed to Vienna, to attend a world conference of Jewish women's organizations from May 6 to 11.

A Castle Sterilizer for Industrial Clinics

Absolutely positive sterilization of all material used is the first essential in all clinics and industrial first aid rooms. There must be no chance of carrying infection from one case to another.

Completeness is the feature of the Castle Sterilizer No. 2019 shown here. It combines in one electrically heated pressure outfit every sterilizing need. It does its work with absolute dependability and accuracy. Send for details and specifications.

"Every office... needs a good sterilizer"

Plans have been made for a \$1,500,000 training school for nurses at Mt. Sinai Hospital. The new structure will be the eighteenth building maintained and supervised by the institution. Half the cost has been promised by the trustees.

Railroad train operation during 1922 occasioned the accidental death of 5,776 persons, the interstate commerce commission reported, and the injury of 47,203 others. In 1921 deaths from similar cause were 5,587 and injuries 43,324, while in 1920 the killed numbered 6,495 and the injured 63,786. Nearly half of the persons killed last year, or 2,424, were trespassers, while 1,236 were trainmen or other employees. Passengers killed during the year numbered 193, against 205 the previous year, while the number of passengers injured was 5,813, compared with 5,584 the year before.

The Judge Baker Foundation is publishing a series of twenty case studies, each one consisting of a separate pamphlet printed in a form that is not only clear and interesting, but is peculiarly adapted to teaching purposes. This series of studies covers a wide range of problems of interest to educators, psychologists, psychiatrists, sociologists, judges, probation officers, and others dealing with matters that involve the adjustments of young people.

The fiftieth annual report of the New York Diet Kitchen Association was made public recently by Mrs. James D. Voorhees, the president. During the last year 6,099 babies were under care from the six baby health stations the association maintains; 6,130 mothers were advised and taught how to give their children intelligent care; 402 expectant mothers registered for supervision; 969 baby conferences were held, to which 37,017 visits were made by babies and their mothers; 1,503 pre-school children examined and supervised who made 6,330 visits to their health classes; 21,450 visits made to homes by the station nurses and assistants, and 516,669 quarts of milk dispensed.

Dr. Royal A. Meeker of Pennsylvania has resigned his position as Chief of the Scientific Division, International Labor Organization of the League of Nations Secretariat at Geneva, to assume duties as State Commissioner of Labor and Industry in Pennsylvania.

Dr. Sofie A. Nordhoff-Jung, member of the staff of Georgetown University Hospital, Washington, D. C., has founded an annual prize of five hundred dollars bearing the title of "The Sofie A. Nordhoff-Jung Cancer Research Prize." The prize, which will be granted for the first time in December, 1923, is destined for the encouragement of researches in the etiology and prevention of cancer.

Vivisection will be among the first subjects considered by the new Bureau of Legal Medicine and Legislation of the American Medical Association, according to a report by Dr. W. C. Woodward, executive secretary of the Bureau.

A course on The Social Aspects of Mental Hygiene is being conducted at Yale University, under the joint auspices of the Department of Social and Political Science of the university and the New Haven Council of Social Agencies. This course is open to the public without charge, and it is planned to publish the series of lectures in book form.

A municipal mental-health clinic has been opened in Pittsburgh, under the auspices of the Department of Charities. It is held at the City-County Building. This clinic accepts persons with mental disorders regardless of their ability to pay for treatment. It is expected to add to the efficiency of the operation of the City Home at Mayview, and to assist the courts and welfare organizations, by examining drug addicts, alcoholics, and other delinquents. This clinic is manned by four psychiatrists and two psychiatric social workers, under the chairmanship of Dr. Edward E. Mayer.

Children's code commissions in North Dakota and Kansas have both recommended that the age of compulsory school attendance for unemployed children who have not completed the twelfth grade be extended to eighteen years and that the minimum educational requirement for children going to work under this age, be the eighth grade. The Kansas Commission recommends that fourteen years be the minimum age at which a child may be employed in any work, including commercialized agriculture, and that sixteen years be the minimum age for the specified hazardous employments. Part-time school attendance is required of working children until they have completed the tenth grade.

A nation-wide survey is being conducted by the Red Cross Directors of Life Saving because of the increasing drownings reported year to year. In the last ten years in the United States there were 58,429 accidental drownings, 6,489 of which were in 1921. By locating the places where drownings take place and co-operating with the community through the Red Cross chapters, a campaign of education is being undertaken, lifebuoys are being placed and life-saving corps organized. The Red Cross has declared war against preventable drownings, and most drownings are preventable. The services of every swimmer in the country are needed to help.

Figures just published show that the population of Australia in December, 1922, was 5,634,000, an increase of 124,000 over the last year.

For financing the industrial standardization work of the United States a plan has been approved by the Executive Committee of the American Engineering Standards Committee, which is expected to provide an annual budget of \$50,000. The plan provides for membership dues on the basis of 1 cent per \$1,000 of gross receipts.

A vigorous campaign against venereal diseases is now being conducted in Indiana. There are sixteen public clinics in the state, and clinics in every correctional institution. For the general public there is a campaign of education through moving pictures, lectures, exhibits and pamphlets.

Pennsylvania State College is offering for the coming summer an eight weeks course in school nursing, designed primarily for nurses who are engaged in, or who desire to become engaged in, nursing work in the public schools. The college also offers about twenty courses in various phases of school health work, one being a four weeks course in nutrition designed primarily for school nurses. College credit will be given when college entrance requirements have been fulfilled.

One person in every seventy-three in the United States today is a confirmed drug addict, according to the reports of narcotic inspectors made to the Treasury Department. The evil is even getting a hold on high school children. Among the organizations for the abolition of the evil, the American Legion is prominent.

AN examination of some of Sherman's Vaccine* prepared *Ten Years* ago showed no apparent deterioration nor autolysis.

We welcome microscopic comparisons of our vaccines, for,—freedom from deterioration and autolytic products, accuracy of count and morphological characteristics.

Bacteriological Laboratories of G. H. SHERMAN, M. D., Detroit

*This vaccine was in druggist's stock in the regular way and recalled as outdated.

Dr. Frank J. Monaghan has been appointed Commissioner of Health for New York City, succeeding Royal S. Copeland, under whom he served as Sanitary Superintendent for the past five years. Dr. Monaghan has practiced medicine extensively and is the author of a number of pamphlets and monographs on various phases of public health work.

A study of the mothers' aid problem in Rhode Island, recently made by Olive S. Webb, at the direction of the General Assembly, shows that there are 554 mothers in the state who need help in caring for their dependent children. It is estimated that the sum of \$192,518 will be required to supply the needed aid. In her report, Miss Webb recommends that aid be given to mothers having children under sixteen, or to those having older children who are unable to work, and that the amount of aid be determined by the individual case. A state bureau of child welfare, independent or established in connection with agencies already existing, was shown by the study to be advisable.

The Industrial Fatigue Research Board announces the publication of three new reports: Report No. 20, "A Study of Efficiency in Fine Linen Weaving," by H. C. Woston; Report No. 21, "Atmospheric Conditions in Cotton Weaving," by S. Wyatt; and Report No. 22, "Some Studies in the Laundry Trade," by May Smith.

Mental hygiene surveys of Arizona, Kentucky, North Dakota, Rhode Island, and Wyoming have recently been conducted by the National Committee for Mental Hygiene. In addition to these, special studies of the mental hygiene needs of Louisville, Kentucky, and of the New York county jails have been made. The survey of Arizona, conducted by Dr. Thomas H. Haines and several assistants, is of especial interest on account of the character of the population. On the whole, the Indian was found to present a less serious educational problem than the Mexican. Among the recommendations made in the report of the survey are the organization of a board of mental hygiene with an executive officer to be called a commissioner, the establishment of a home and training school for mental defectives, and the supervision in the community of those mentally defective persons who do not require institutional care. The Wyoming survey was begun in November, 1922, and is now drawing to a close.

That the mental hygiene movement has become universal in scope is evidenced by the recently formulated plan to establish an international committee for the purpose of co-ordinating the work of the leagues existent in the individual nations. The plan was conceived by Mr. Clifford W. Beers, author of "*A Mind That Found Itself*," and founder of the mental hygiene movement; and has found favor with the majority of psychopathic experts. At the meeting of the organizing committee in December, it was arranged that the First International Congress on Mental Hygiene be held in the early part of June, 1924, in the United States.

A conference was held recently at Harrisburg, Pa., to discuss the activities of the Bureau of Animal Industry in the State Department of Agriculture and the question of procuring adequate funds for carrying on the work. The importance of continuing the study, prevention and control of tuberculosis, hog cholera and miscellaneous and transmissible diseases of animals and poultry was emphasized. Various live-stock associations, milk producers' associations, the Pennsylvania State Bankers' Association, the Pennsylvania Tuberculosis Society and other organizations have indicated their approval of the movement.

The Graduate School of Social Service Administration, the University of Chicago, is offering to its seventy students in training for social work a course on the psychiatric basis of social work, to begin the early part of February. It will include a general survey of the psychiatric problems underlying social work and will deal with the methods of diagnosis and treatment employed by psychiatrists, with special reference to the psychiatrist's approach to such problems as juvenile and adult delinquency, industrial maladjustment, family disorganization, and problems of personality.

An ambitious program has been adopted for the ensuing year at a recent meeting of the executives of the Virginia Tuberculosis Association. The list of projects includes the establishment of permanent tuberculosis clinics in cooperation with the State Board of Health, work in the public schools, and survey of the industries to determine to what extent medical and nursing service is being used and to stimulate such were absent. Among the recent activities of the As-

sociation is the issue of an attractive health play for two characters, entitled "The Health Fairy and the Witch," which may be secured by writing the Association at Room 611, Chamber of Commerce Building, Richmond, Va.

Diagnostic service for tropical and exotic diseases will be provided by the Department of Tropical Medicine of the Harvard Medical School, acting through the members of the medical profession generally. The Department will act in affiliation with the Service for Tropical Diseases at the Boston City Hospital.

Two measures are pending before the New York state legislature which would reduce the non-compensated waiting period in industrial accidents from fourteen to seven days, and would provide for compensation from date of accident if the injury extended over twenty-eight days instead of forty-nine as at present. According to State Industrial Commissioner Bernard L. Shientag, the state should assume the unjust burden carried by the injured and their families when industrial accidents come within the limited waiting period. In twenty-one states the waiting period is one week, and in seven the period is ten days.

The first nutrition institute ever held in Texas was conducted under the auspices of the home economics division of the Bureau of Extension at the University of Texas, Feb. 5-7. Many pediatricians, nutrition specialists, child welfare specialists, public health and Red Cross nurses, and home economics teachers attended. The purpose of the institute is to give to the nurse the latest information and developments along nutrition lines, particularly in relation to the pre-school and school child.

At least two states are systematically getting before the medical and health contingents on the voting public an analytical comment on pending legislation. The *Ohio State Medical Journal* for February presents all important bills now under way. In the February issue of *Better Health* the League for the Conservation of Public Health, an organization which has accomplished unique team work between professional men and laymen, offers critical comment on some seventy measures on which it is in position to make recommendations.

KOTEX

Confidence

PRICELESS to women is sense of well-being, of self-confidence and poise. To be sure of one's self in any emergency, in any costume, and on any occasion—is indeed worth much.

Women have found in Kotex both assurance and comfort. Kotex makes it possible to wear the daintiest frocks with a sense of safety, and to attend to one's regular occupation or social engagements without discomfort.

Kotex are available in good stores everywhere—dry goods, drug and department stores. They are far superior to other sanitary pads and make-shifts.

Ask for them by Name

How We Resist Disease: An Introduction to Immunity

According to the author's, as well as the publisher's, blurb (to use the neologism of Brander Mathews), "How We Resist Disease" has been designed to meet the needs of an elementary course in immunology for nurses and general college students. We must congratulate Professor Broadhurst of Teacher's College, Columbia University, on the brilliance and adroitness with which she has consummated this difficult task. There are few, if any, sciences in the biological and medical fields which are more nearly sciences of *phenomena* rather than *facts* than immunology. And, correspondingly, there are few more difficult for the elementary student to comprehend or the pedagogue to teach. Because of its simple, lucid text, its wealth of illustrations (there is a figure on nearly every page!) and particularly because of the valuable descriptive material which accompanies the cuts, this book is a real contribution to the field. It is perhaps unfortunate that chemical analogies are not used more commonly in place of the time-worn (and patience-wearing) pictorial analogies. There is certainly as good theoretical justification for them and one is inclined to suspect that they are even more readily comprehended by the student who has had a single course in chemistry. However, even such criticism is gratuitous. The text is warmly recommended as well to the teacher of the first principles of infection and immunity and to the busy lay or professional person who has only a few hours or an occasional leisure minute in which to reestablish contacts with the ground-plan of immune phenomena and methods.

J. B. Lippincott Company, 1923, Svo; 248 pp.; 138 illustrations.

Foods of the Foreign Born

Some of the most serious problems of nutrition in this country arise from the contrast between the rural surroundings in which our immigrants have grown up and the complex urban environment in which they find themselves here. Miss Bertha M. Wood who is the dietitian of the food clinic of the Boston Dispensary discusses some of the particular hardships experienced by certain races such as the difficulty which Italians find in obtaining the milk, vegetables and eggs to which they are accustomed at home, (complicated by the habit of feeding infants as soon as

they are out of swaddling clothes on adult diet with the maximum distention of the abdomen as an ideal), a similar lack of milk in the Polish diet in this country and the shortage of milk and vegetables with an excess of pickles in the Jewish dietary. If dietitians are to secure results it is most essential that they should understand the religious and racial prejudices of the races with which they deal and should be able to express dietetic principles in the language of the foreign-born. The most important part of Miss Wood's book is a series of recipes for national dishes which appeal to Mexicans, Portuguese, Italians, Hungarians, Poles and other Slavic peoples, immigrants from the Near East and Jews, with particular emphasis on the national dishes suitable for undernourished children, diabetics, etc. The admirable suggestion is made that in institutions receiving foreign-born inmates an international menu should be provided containing each day at least one dish especially adapted to one of the nationalities or races represented. Furthermore there is much for us to learn as well as to teach and the American diet would be improved and enriched by the inclusion of many of the excellent dishes described in this helpful work.

Whitcomb and Barrows, Boston, 1922, 98 pp. + ix.

An Introduction into World Politics

Since the birth of nationalism and the complexities of the nineteenth century, the problems of international relationships have been of ever increasing importance. Our stability and existence in the future will depend in large part upon the reasonableness in the adjustment of these disputes, and careful and painstaking assembly of considerations such as this book by Herbert Adams Gibbons includes warrants the most studious perusal.

The Century Company, New York, 1922.

Civic Education

The author, David Snedden, discusses and analyzes the needs and possibilities for purposive and effectual objectives and the means of civic education. He is convinced that the aims or objectives of any proposed type of education must be derived from studies of the needs of contemporary societies, evidenced in the adult members. The greater portion of citizens cannot be trained to assemble data and derive conclusions

concerning social problems any more than they can provide their own dental or surgical service. "Somehow citizens must be so educated in civic matters that they will know when and where to rely upon conclusions reached by themselves, and under what circumstances to seek the guidance of experts, to appreciate and know that which will qualify them to select and use the right experts." Dr. Snedden points out the need for specific terminology and civic education as a part of general education.

World Book Company, Yonkers-on-the-Hudson, New York, 1922.

Market Milk

This timely contribution by two well known milk specialists, Ernest Kelly, in charge of market milk investigations, and Clarence E. Clement, market milk specialist, Dairy Division, Bureau of Animal Industry, U. S. Department of Agriculture, deals concisely with the theory and practice of the various phases of the market milk industry. It should prove helpful to anyone interested in problems of milk production and distribution, especially to dairy students and health officials.

John Wiley & Sons, Inc., New York, 1923.

Lewis H. Carris Heads National Committee

Lewis H. Carris, formerly administrative head for the Federal Board for Vocational Education, has been selected to succeed Edward M. Van Cleve as managing director of the National Committee for the Prevention of Blindness. Mr. Carris is by training and social experience particularly fitted to carry on the excellently well conducted program conducted by Mr. Van Cleve. During recent months he has served the Committee in field investigations which put him in immediate position to assume intelligent executive direction.

In losing the administrative efforts of Mr. Van Cleve, the Committee must place to the credit of his energy and vision a program of amelioration that has been singularly effectual and productive of public opinion and legislative effort which promises increased support of the movement from year to year.

The budget proposed by Governor Richardson of California will require the health forces of the state to operate with a reduction of \$112,730.96 from the present schedule.

In Cases of Stasis

Stanolind Liquid Paraffin

(Heavy)

Is Indicated

TODAY THE PHYSICIAN PRESCRIBES medicines only when their use is definitely, specifically indicated.

Wherever possible he obtains the desired results by methods which are mechanical, for in this way he avoids the danger of overtaxing the vital organs and obviates the likelihood of his patient forming a habit which may prove disastrous.

That is the reason why Stanolind Liquid Paraffin (Heavy) has won a place for itself among those physicians who have tried it.

Stanolind Liquid Paraffin (Heavy) is a rich, heavy-bodied, mineral white oil of ideal viscosity and correct specific gravity for the treatment of intestinal stasis and correlated ills.

Stanolind Liquid Paraffin is sharply distinguished not only in chemical composition, but also in its physiological action, from oils and fats of vegetable and animal origin. It undergoes no change in the course of its passage through the intestines. It is neither digested nor absorbed. Its primary action is entirely mechanical, keeping the intestinal contents soft, and lubricating the alimentary tract.

Physicians who have heretofore avoided medicinal mineral oils of domestic origin, will appreciate the unusually high viscosity of Stanolind Liquid Paraffin (Heavy)—300-310 Saybolt at 37.7 degrees C (100 degrees F); specific gravity — 0.891 — 0.895 at 15 degrees C (59 degrees F).

Stanolind Liquid Paraffin

(HEAVY)

Tasteless - Odorless - Colorless

Manufactured only by the Standard Oil Company (Indiana)

Body Mechanics and Health By Thomas and Goldthwait

The thesis advanced by Miss L. C. Thomas and Dr. J. E. Goldthwait is that "until a person understood good body mechanics and has gained the correct muscular coordination, chiefly of the abdomen, chest, and back exercise is of little benefit and often is harmful." The writers point out that children at least find ample opportunities in normal play for the exercise of the arm and leg muscles, and they believe that formal gymnastics should primarily emphasize the problems of posture and the development of a consciousness of postural control which is often wholly lacking. This is of course particularly necessary for the slender visceroprotic ("carnivorous") type which includes the majority of children. The rules for acquiring and maintaining proper body mechanics are so few and simple that they offer little excuse for negligence, requiring emphasis on the maxims "stand tall, head up, chin in, chest high, abdomen flat, weight on balls of feet." After a general discussion of the principles of postural control the authors give us an excellent series of progressive exercises designed to develop it and the teachings of the little book are emphasized by well chosen and unusually effective illustrations. This little book should prove of very real value not only to teachers of physical education but to everyone who has an intelligent interest in the problems of personal hygiene and who appreciates the motto quoted by the authors from Milton "Nature has done her best; do thou thine."

Houghton Mifflin Company, Boston, 112 pp.

Typhoid Fever in 1922

The annual summary of typhoid fever death rates that appeared in the March 10, issue of the *Journal of the A. M. A.*, shows that the slight interruption to the downward trend of the typhoid mortality curve that occurred in 1921, was more than overcome in 1922. The astonishing rate of 3.15 has been attained. In the editorial comment of the *Journal* for the following week it states:

This is a little less than one-sixth of the rate (19.59) for the large cities of this country in 1910. Three cities with an aggregate population of 473,975 were able to report a perfectly clean slate, not a single death from typhoid having occurred within their borders during the calendar year 1922. The main causes of indigenous urban typhoid in the United

States at present seem to be contact with typhoid cases and typhoid carriers—a steadily diminishing hazard, occasional cases from contaminated shellfish and from bathing in polluted water, and, perhaps in some cities, from the improper disposal of excreta. Relatively few cases appear to be caused by polluted drinking-water, by milk supply, or, in the Northern cities by inadequate sewerage.

The two great agencies of typhoid dissemination, polluted water supplies and raw milk, are largely eliminated, and while cities of from 10,000 to 100,000 population have unquestionably much progress to make, especially in control of the milk supply, the condition in the larger cities for the most part may now be regarded with pride instead of being pointed to with obloquy as awful examples.

The Science of Ourselves

The thesis of "The Science of Ourselves" by Sir Bamfylde Fuller is to show the evolution of conscious life and the expression of feeling and thought in behavior. It is not surprising to find innate mental capacities bound up with physical susceptibilities. The energy generated from motor excitement converted on the physical plane manifests itself as emotion. Through the activities of the brain, feelings, physical and psychic, are combined with ideas of them. The ideas themselves, whether impression, record, or concept, are material things represented by some sort of actual impress on a brain cell.

The relationships which develop are a result of coincidence or sequence in rhythm—mental associations are connected by familiarity of rhythm. Imagination and reason proceeds solely on the basis of individual experience. Conscious choice of the material of thought is colored by likes and dislikes—prejudice becomes unduly operative by some overcharge of emotions. Ideals become effective controlling motives only as experience tends to confirm their general truth. Reactions repeat themselves till useful habit is confirmed. Traits of character result from peculiar sensibilities of individuals to particular stimuli. By practice is evolved those complicated "tastes" which are artificially associated with certain stimuli and become objects of choice.

It is only by habit of mind that certain social objectives become inspiring. Civilization, after all, is an artificial product that does not "take" if the plastic period of childhood is not reserved for intelligent training. In the interest of human happiness certain ideals must be more generally inculcated and they are difficult to teach because the uncompromising

logic of the young minds demand a better conformity than their teachers usually evince.

Though the tenets of this book may seem disillusioning, a clear understanding of the physical basis of mental reaction will lead to a more general insistence upon sound inheritance, and to expect the achievement of satisfactory mental adjustment through good health and consistent nurture rather than through further idealization and self-deception. It cannot be claimed that illusion has been successful; and there is a case for bringing the mainstays of our behavior under the light.

Oxford University Press, New York, 1921.

Industry and Human Welfare

"Industry and Human Welfare" by William L. Cheney, which is a volume of the Social Welfare Library edited by Dr. Edward T. Devine is an attempt to trace the development of industrial-social problems, particularly those affecting the worker and the family of the worker. The development of modern industry has added greatly to the wealth, progress and comfort of mankind, but it has also produced conditions which are inimical to the welfare of industrial workers and to the community as a whole. Mr. Cheney shows how such problems as those arising out of the industrial employment of women and children, long hours, inadequate wages, irregular employment, accident and health hazards, and the like have developed as our factory system has grown in size and complexity. He traces the growth of sentiment for the protection of the interests of workers and gives a brief history of the development of legislative and other means of insuring that protection.

There have come some very striking changes in society's definition of what is socially wholesome. One is the change in its attitude toward child labor which is admirably set forth in these two sentences:—"In 1800 the employment of children was counted a discipline leading to virtue as well as a source of proper profit for their parents and guardians. At present employment of children in industry or agriculture is known to be a serious handicap to their normal development as workers and as citizens." Perhaps in the increasing public interest in these problems which Mr. Cheney depicts lies the best promise of their solution.

Public Economy and Public Health*

Human Wastage the Crime of Our Present Civilization

By HARRY H. MOORE, UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

AS THESE lines are being written, thousands of newspapers are informing millions of readers of the accidental death in a Pennsylvania coal mine of seventy-six or more miners. But even while the people are reading the tragic news, dramatically related, other miners and carpenters and merchants and lawyers, and men, women, and children of all kinds are dying in the United States of preventable or postponable diseases at the rate of over sixty per hour, every hour of the day and every day of the year¹. Disasters such as mine explosions arouse popular sympathy and widespread remonstrance; they result in a demand for more careful inspection, for the purchase of safety devices, and for other preventive measures, regardless of cost. The needless death of hundreds of persons every day under less dramatic conditions has become so commonplace that few are moved to protest—to demand that adequate preventive measures be inaugurated and that sufficient funds be provided

A positive health program has never been made a popular objective, but health practices, along with other ethical systems, have been more a means of group control than self imposed routine day-by-day codes of action.

It may well be considered that health work has lagged, not because of retarded scientific achievement, but because health activities have not found their status proper in economic organization and because the public has not counted the economic recklessness of tolerating preventable disease.

to make such measures possible. The conquest of disease is largely a matter of available money. The appalling waste of human life in the United States will continue until this fact is understood by the appropriating bodies of local, state, and Federal governments.

Health Appropriations Meager

The dearth of trained men, the curtailment of scientific research, the scarcity of educational materials, the lack of dispensaries and other equipment are due largely to the meagerness of appropriations for official health agencies. The amounts appropriated for the health activities of

various units of government will be briefly discussed.

For several years the Federal government has appropriated approximately one hundred million dollars annually for the construction of rural post roads², with the provision that each state accepting its allotment of this fund appropriate a like amount. But a similar plan for the development of rural health work in cooperation with the states provides for an appropriation of only fifty thousand dollars per year³ (Fig 1). Although the money has been used so effectively that it has stimulated the expenditure by county and state governments of amounts five or six times as large as the Federal fund, it has appeared impossible to have the subsidy for health work increased. Only 216 of the three thousand counties of the United States were equipped at the end of 1922 with full-time county health officers (although in a few additional counties there were full-time public health nurses), yet the amount of money expended for a single mile of paved highway⁴ would provide a county with a health officer, a sanitary inspector, and one or more public health nurses, for an entire year, and there would be money left over for other expenses. No thoughtful sanitarian would begrudge the money used for good roads—he knows they bring the farmer into closer touch with the rural physician and nurse. He would not have less spent for roads, but he

*This article appears as Chapter XX in Mr. Moore's forthcoming book, "Public Health in the United States—an Outline with Statistical Data." In earlier chapters Mr. Moore deals with the human and economic costs of disease, the warfare against disease, various types of organized health work, and with economic and sociological aspects of public health. In this chapter certain additional data are presented emphasizing the meagerness of appropriations for health work and showing that it would be profitable from an economic standpoint to make larger sums available. The book will be issued in July as the first volume of "The Public Health Series," edited by A. J. McLaughlin and published by Harper & Brothers, New York City.

would have more spent for health work.

Although it may not be generally known, the Federal government assists the states in the maintenance of the national guard. The amount appropriated for such aid for the year 1923-24 was \$29,800,000. If only one-half of this money were available for rural health work and if it were matched by states and counties acting jointly, it would be possible to place a full-time health officer at \$4,500 per year and a public health nurse at \$2,500, with an expense fund of about \$3,000, in each of the three thousand counties of the United States. The same thing might be done if only three per cent of the total amount provided for the Army and Navy by the budget for the same year, were available⁵.

Municipal Health Departments

During 1921, 183 of the 253 cities of the United States having a population of over 30,000 expended for all municipal activities⁶, \$873,385,081. Only \$20,475,626—less than 2½ per cent of this amount—was used for the "conservation of health" (Fig. 2). This term (as defined by the Bureau of the Census, which compiled these figures) includes health administration, vital statistics, prevention and treatment of communicable diseases, conservation of child life, food regulation and inspection. A somewhat larger amount, it will be observed from the graph, was appropriated for "sanitation or the promotion of cleanliness," (which in some cities come under the jurisdiction of the department of health) including sewers (their construction presumably) and sewage disposal; street cleaning; other refuse collection and disposal; public convenience stations; other sanitation or promotion of cleanliness. The total of these two amounts, however, is less than the sum expended for police and other "protection to person and property" (not including fire protection). Only a little more was spent on sanitation and health combined than on highways.

State Health Departments

In 1916, about five million dollars was appropriated by all the states to their departments of health⁷, but, the year previous, over forty-five million dollars⁸ was used for the maintenance

Fig. 1.—Expenditures for 1923-24, according to estimate of the Budget Bureau: \$100,000,000 for subsidies to promote the building of rural post roads; \$50,000 for subsidies to promote rural health work.

of subsidized institutions for the insane, epileptic, tuberculous, leprosy, blind, deaf, deformed and feeble-minded⁹. The hospitals for the insane provided care for only 199,000 patients, when, it will be remembered there are in the country at least 350,-

000 insane persons, who ought to have hospital care. In 1922, all the states were expending for public health work about eleven and one half million dollars; and at that time the institutional care of the defective and sick was costing about sixty to seventy-five million dollars (the exact figures are not available). Although the former amount does not include what is spent by municipalities within the various states, it would seem desirable, merely from the standpoint of economy, for the states to spend more money for prevention, at least for the prevention of tuberculosis, insanity, and other disorders and defects which are so expensive to the commonwealth. The graph (Fig. 3) shows the relation of the amount spent by the states for public health to the amount paid for the institutional care of the sick and defective.

Federal Health Activities

A graph prepared by the Bureau of the Budget¹⁰ shows that only 4/10 of 1 per cent of the total amount provided by the 1923-24 budget was for the promotion of public health by all agencies of the federal government. Figure 4 compares in terms of dollars the estimated expenditures for public health with estimates for other gov-

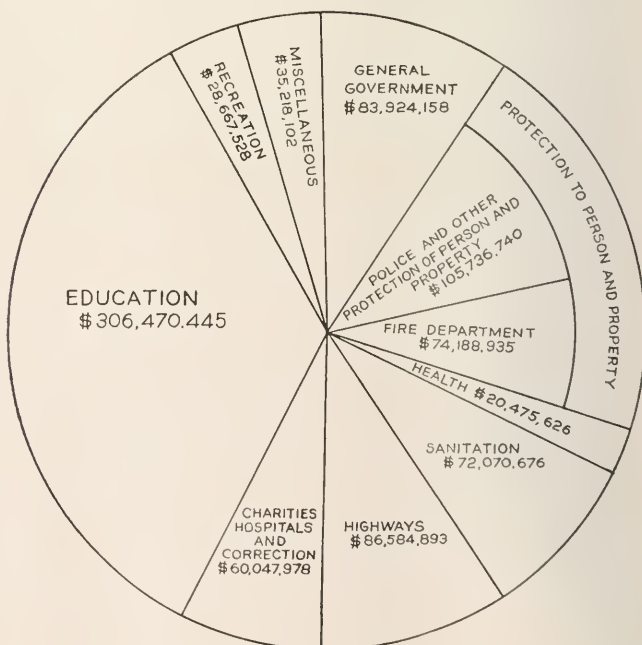

Fig. 2.—Amounts expended by 187 large cities of the United States in 1921 for various purposes.

ernmental agencies and activities¹¹. The annual appropriations to the United States Public Health Service are pitifully inadequate. "Congress with rare vision," says the *Journal of the American Medical Association*¹² "established some twenty years ago the Hygienic Laboratory of the United States Public Health Service. The staff has included some of the foremost representatives of chemistry, pharmacology, bacteriology, and medical zoology—the specialties most needed for a cooperative attack on the great problems of health in the country. But subsequent Congresses have failed to provide for any considerable growth of this laboratory . . . The people of this country spend \$500,000,000* a year on drugs in addition to other large sums for other means of obtaining relief from suffering and disease. Would it not 'pay' to spend a million or two a year to determine whether this great drug bill could not be reduced by the discovery of better, fewer, and cheaper drugs as well as of other means of preventing disease and of obtaining relief from pain?"

Funds Generally Meager

The total expended by all official agencies for public health work in 1922 was about sixty millions of dollars (Table 1). Yet at the same time

TABLE 1.—APPROXIMATE EXPENDITURES BY ALL OFFICIAL HEALTH AGENCIES FOR THE THREE YEARS ENDING 1922¹³

	1920	1921	1922
States ¹⁴	\$10,000,000	\$11,000,000	\$11,500,000
Cities ¹⁵	20,000,000	28,000,000	28,000,000
Rural ¹⁶	5,000,000	5,000,000	5,000,000
Federal ¹⁷	25,000,000	21,000,000	15,000,000
Totals	\$60,000,000	\$65,000,000	\$59,500,000

the people of the United States were spending over one thousand millions a

*This estimate of the American Medical Association is a little larger than that given at the beginning of the discussion of this subject in Chapter 3, and used also in the next paragraph.

Fig. 4.—Budget Bureau's estimate of expenditures for the year 1923-24 for various departments and bureaus of the Federal Government.

year for hospital service, physicians, healers, and nurses, and, in addition, about three hundred and fifty millions for drugs—a total of approximately one thousand four hundred millions of dollars, to say nothing about the cost of premature death and the loss in time and efficiency caused by disease¹⁸. And it should be remembered that most physicians, healers, and nurses are engaged in curing diseases which efficient health work might have prevented, and that much of the medicine purchased is worse than useless.

The appropriating bodies of county, municipal, state, and Federal governments are demanding that appropriations for public health be kept down, because taxes have become so high as to be a burden to the people. In the light of the data set forth in the preceding pages, however, such an excuse for not adequately supporting health work seems hardly valid. So exceedingly small is the percentage of public funds spent in the United States for health activities that to double or treble the amount would make hardly a perceptible difference in the tax bill. Furthermore, a small

increase now in expenditures for health work would tend to reduce future taxes for the upkeep of various state institutions.

Surely a nation rich enough to spend over one thousand eight hundred million dollars a year on tobacco (Fig. 5) and eight hundred millions on confectionery would be willing (were the people persuaded to reflect upon the situation) to spend more than a paltry sixty million per year on its official health agencies. The most that can be said about chewing gum is that it probably does not do much harm; some physiologists believe that it has a detrimental effect on the digestive processes. Yet the people of the United States are paying each year more money for chewing gum than they appropriate through legislative bodies to all official agencies for public health activities. What will future generations say when they contemplate this fact and when they observe that we are now spending even more for perfumery and cosmetics¹⁹?

The tax alone on candy, collected by the Federal government for 1921, if used for public health purposes, would have made available a considerably larger amount than was allotted by the 1923-4 Federal budget for the promotion of public health by all departments of the government²⁰. If for the purpose of waging a more vigorous attack on disease, cigarettes were taxed just a trifle more than they are now (\$3.60 per thousand, instead of three dollars as at present) and other kinds of tobacco proportionally, it would be possible almost to double the amount now available for the health work of local, state and federal agencies combined²¹.

Fig. 3.—Amounts expended by the people of all the states through their state governments for health work and for the care of defective persons in institutions.

Of the economic profitableness of health work evidence has been presented indicating that disease costs the nation vast sums of money, that preventive measures definitely and promptly reduce both the amount of sickness and the number of deaths; and it has been obvious in many instances that such reductions result specifically in the saving of money.

When a man pays a physician fifty dollars to attend over a period of a year various members of his family who suffer from malaria, and then, after paying only one dollar extra on his tax bill *** for the inauguration of a program of malaria control measures, he finds that he has not had to call a doctor for twelve months on account of this disease—after such an experience, not uncommon in the South, there is no question in one's mind regarding the profitableness of at least this type of public health work.

The Metropolitan Life Insurance Company found that among its industrial policy-holders there were 55,000 fewer deaths in 1921 than there would have been had the 1911 death rate prevailed. It believes that "a very great factor" in this tremendous saving of human life was the "health campaign carried on by the Metropolitan itself." It was profitable to the company in 1921 to distribute eighteen million copies of its health magazine and, in addition, twenty-five million pamphlets; to conduct 144 health exhibits and emergency hospitals at county fairs; 295 "clean-up" campaigns; nationwide attacks against special diseases, and various sickness and sanitary surveys; to detail its agents to assist in the promotion of health legislation; to lend its leadership in research work related to influenza; and to send its trained nurses on 2,111,875 visits to policyholders. In addition, it appears to have been "good business" for this company to spend thousands of dollars in health publicity among the leading magazines of the country²².

It has been profitable, as has been seen, for many industries in the United States to invest \$2.00 to \$11.00 per employee, per annum, for health service.²³ When absenteeism and accidents are reduced, dollars are actually saved. One firm, it will be remembered, made a net saving of over forty thousand dollars by establishing a health service.

The main purpose of public health work is not to save money, but to

Fig. 5.—Estimated amounts of money spent by the people of the United States during one year (in 1919, except when otherwise indicated) for various purposes indicated. The five amounts at the left were obtained by adding to the "value at factory" 80 per cent for freight and express, advertising, profit of jobbers, profit of retailers, and other costs of marketing.

make possible for all the people the freer, fuller, more buoyant life; we must have health work regardless of its cost. But it is desirable to point out in passing that a public health program "pays" from the standpoint of saving money; and local, state and federal governments could profitably double or treble their appropriations.

The achievements of the past fifty years in preventing smallpox, yellow fever, malaria, bubonic plague, typhoid fever, and hookworm disease; in reducing the mortality due to diphtheria; in lowering the general and the infant death rates and increasing the span of life, gives strong support to the hope that tuberculosis, syphilis and gonorrhea, influenza, poliomyelitis, the mental diseases, pneumonia, cancer, and diseases of the heart and kidneys may also be greatly reduced. "Within natural limitations any community can determine its own death rate," affirms and reiterates the New York State Department of Health; and, what is as important, money will buy health and make possible a higher degree of efficiency and a fuller joy in living.

1. 1,390,000 deaths per year (on the basis of 1,142,558 for registration area) means over 3,800 per day or 158 per hour. Assuming that 40 per cent are preventable or postponable, there are, therefore, over 60 deaths per hour preventable or postponable.

Water Sports as Municipal Recreation

BY MABEL TRAVIS WOOD, PLAYGROUND AND RECREATION ASSOCIATION OF AMERICA.

EVERY year the old jest that cities are the most popular summer resorts in the world acquires a little more truth. In spite of scorching pavements and breezeless apartment houses, cities are becoming more and more pleasant and healthful places in which to live in summer. Municipal departments of recreation are providing park play spaces, playgrounds, tennis courts and recreation piers. One of the chief ways in which they are keeping their population happy during hot weather is through water sports. For humanity turns naturally to water when the mercury is high.

The green depths of the "old swimmin' hole" beckoned alluringly to the boy of a generation ago. The lure of water is just as strong for modern youngsters whose activities are curtailed by streets and walls. "The gang" sneak off to the dock and splash eagerly into the appealing element. Its purity may be questionable, but the fact that it is water is sufficient for them. A group of urchins minus a playground, but plus a gutter pool and a warm afternoon, always results in a miniature Coney Island. As for the real Coney Islands, they swarm with city-dwellers of all ages.

Water sports under proper conditions are healthfully recreative. Unsupervised they may prove a menace to life and health. For both these reasons cities have been giving them an important place on their summer recreation programs. One hundred and twenty-seven cities reported to the 1922 Year Book of the Playground

and Recreation Association of America that they were providing bathing beaches, and one hundred and eighty cities that they were providing swimming pools for their citizens. Listed among civic duties we now find teaching every boy and girl to swim and furnishing places where they may swim in safety. Sanitary municipal pools, both indoor and outdoor types, municipal beaches and playground wading pools are supplying hot weather fun and comfort to millions.

They are doing it at a nominal cost. "It is cheaper to pay taxes for municipal recreation than to buy expensive commercial recreation," says the superintendent of the efficient system of recreation in Oakland, California. A swim in one of Oakland's municipal pools costs the city only ten cents, while in a commercial pool the cost of a swim to an individual averages sixty cents. Bond issues for water sport facilities are becoming increasingly common. Memphis, Tennessee, recently appropriated \$100,000 for a public swimming pool.

Many municipal pools and beaches have been constructed as a direct result of the toll in lives taken by some river or lake. "Keep away from the river and the canal; they're dangerous," young people of Middletown, Ohio, were warned. Then Middletown awoke to the fact that it should be providing some legitimate outlet for this desire for the water. Street shower baths, under the cooling spray of fire hoses, were tried and proved immensely popular with the children. And last September a fine new mu-

nicipal pool was opened. One side is shaded by trees. Another is bordered by a sandy beach fifteen feet wide. There are rustic bath houses, a diving tower, spring boards and a chute-the-chute. Hundreds could not wait until the formal opening of the pool and took a dip while the contractors were still at work.

Municipal Beaches

Cities fortunate enough to have either ocean frontage, or a clean lake or river have equipped these natural bathing resources for safe water recreation. The municipal beach is, besides a place for bathing, an outdoor playground where families may go to spend an afternoon or a holiday. It offers sand and waves and refreshing breezes without catch-penny attractions and with assured sanitation and orderliness. Cities provide bath houses and water sport equipment, maintain life guard service and often supply swimming instructors.

An island in the Susquehanna River, across the way from the city park of Harrisburg, Pennsylvania, was made into a municipal bathing beach and opened to the public in June, 1921. It has proved a magnet to city dwellers, attracting thousands every summer day. This is an excellent example of how a natural facility, improved, can be increased in service manifold. Before Harrisburg floated a loan of \$40,000 for the improvement of the beach and the erection of concrete bath houses, the site had been used for bathing only by an occasional few. There had been two inadequate

Wading pools supply hot weather fun and comfort to playground frequenters.

Bathing beach operated by the department of parks, New Bedford, Mass., and self-sustaining.

and primitive wooden bath houses. The new bath houses have lockers, shower baths, drinking fountains, and electric lights. There is no charge for swimming privileges and bathing suits are supplied at a nominal fee. A first aid tent has been erected and life

used for skating, and thus their recreational value is extended. The most favored shape is oval. Long, narrow dimensions prevent unskilled swimmers from getting too far from shore and enable life guards to more quickly reach those in trouble. Con-

ing from fifteen inches to a maximum of ten feet, eight inches, accommodates every class of swimmer from beginners to experts. A concrete pool at Pierre, South Dakota, also constructed largely by volunteer labor, is near a supervised playground. Both pool and playground are lighted and kept open until ten o'clock on summer evenings. A unique feature of this pool is the fact that the water comes from a natural gas well and flows in at a temperature of 96 degrees Fahrenheit the year round. This makes it possible for lovers of swimming to indulge in the sport much earlier and much later than they could in the average outdoor pool.

A recent tendency is to make artificial outdoor pools resemble as closely as possible a spot arranged by nature for man's delectation. A little distance from Chicago factories and smokestacks is the new Columbus Park combination swimming and wading pool. But it is shut off from urban things by real country hedges. Elm, maple and ash trees have been planted in the background, and there is an undergrowth of hawthorn, sumac, wild plum and cherry. Ledges of rock give the sides a very natural appearance, and the pool is fed by a little waterfall, supplemented by several hidden supply pipes.

Keeping the outdoor pool sanitary is accomplished in different ways by different cities. There is generally a constant flow of running, filtered water, and the entire body of water is changed regularly. While the pool is empty it is thoroughly scrubbed with brushes. Most cities have the water examined for bacteria at regular intervals. Purification of the water between changings is accomplished by the use of hypochlorate of lime, copper sulphate or other chemicals, or by treating it with ultra-violet rays. Bathers are everywhere requested to take a shower before entering the pool. This serves as a sanitary measure and also prepares the bather for his plunge.

To make sure that no persons with infectious diseases enter the pools, many cities make passing a medical examination a requirement for bathing privileges. At the larger St. Louis pools a physician is constantly on hand to render first aid and to inspect the bathers as they enter the pool. Although this inspection is necessarily superficial, any infectious skin disease would probably be detected. Often it has been found better from a health standpoint to supply bathing suits at a nominal charge than to let the bathers bring their own suits. The

The youngest citizens are not forgotten.

Community Service

guards watch over the safety of the bathers.

Transforming an abandoned pond, which had once been used for cutting ice, into a successful swimming beach, was accomplished in Brockton, Massachusetts, through cooperation of the entire city under the direction of Brockton Community Service. The mayor and two hundred citizens donned overalls one Saturday afternoon and cleared the shore of boulders. The city supplied sand. An old two-story hen house, located two hundred feet from the beach, was turned into a modern bath house with dressing rooms and showers through the volunteer work of masons, carpenters and plumbers. Now Brockton's water playground fills an important need in its recreational life. The water carnival staged there each summer is a gala event for the whole city.

Cities without natural bathing facilities have constructed artificial pools for outdoor summer use. Often such pools are used to supplement natural facilities. Given a small piece of ground available for play purposes, a city can utilize it to no more popular or intensive advantage than by building a swimming pool upon it. In the winter these outdoor pools may be

crete is the usual material. Many pools are provided with lights so that they may be kept open at night. At Jackson Park beach, in Chicago, flood lighting from the shore makes bathing at night almost as safe as it would be in the daytime. Reflectors project powerful rays down upon the water. Service to men, especially in an industrial community, makes evening operation necessary. The use of the pools at this time is generally limited to working men and boys.

Outdoor Swimming Pools

Detroit provides sixteen outdoor swimming pools in different parts of the city. Grand Rapids has thirteen, in charge of a corps of life guards who look like college athletes and who are selected for intelligence and for qualities of leadership. An interesting municipal pool was built at Johnstown, Pennsylvania, during a period of industrial depression and much of the work was contributed. Local firms supplied practically all of the materials free of charge. Though the completed pool is an improvement valued at more than \$60,000, the actual cost of construction to the city was \$11,000. The pool is 250 feet long and 165 feet wide, and the depth, increas-

West Park system in Chicago had been asking those who used its pools to furnish their own suits and towels. The dry goods stores in the district began to complain that their sales in children's underwear had materially decreased. It was discovered that many mothers were making for their children trunks which served the dual purpose of underclothing and bathing suit! The danger was obvious. Now the West Park system supplies suits, soap and towels free. No disease or contagion has ever been traced to its pools.

Children's Wading Pools

The youngest citizens are not forgotten when cities supply water sport facilities. Few children's playgrounds nowadays are considered amply equipped for summer fun unless they have a wading pool. Such pools are usually made of concrete with curb walls high enough to serve as a seat. Occasionally they have a bottom of sand, which allows the water to filter away through the soil or to evaporate, and which is soft and yielding for small feet. Dressing rooms are supplied in a nearby field house, also facilities for the shower bath each child is required to take before entering the pool. Often a sand court adjoins the pool, and seats are arranged under a canopy for mothers who wish to watch the youngsters enjoying themselves in the cool water or on the miniature beach. The wading pool serves to acquaint little children with the water and makes it easier to teach them to swim when they are older.

Popular Water Sports

Swimming is fun enough in itself, but lately water games of all kinds have come into prominence and have added to the recreation possibilities of the municipal pool or beach. Basketball, push ball, volley ball and baseball are among the games played on land which may be adapted to playing in the water. Other interesting possibilities are obstacle races, tugs of war, wrestling in shallow water and potato relays. All these games are described in a chapter on water sports in the handbook "Recreative Athletics" issued by Community Service, 315 Fourth Avenue, New York City.

As part of their summer recreation program, cities have been setting aside days for organized water sports. Among the events are swimming and canoe races, fancy diving and water games. Music and dramatics sometimes have a part, as at Harrisburg, Pennsylvania's annual "Kipona" or

Swimming pool erected by the local community service, Rocky Mount, N. C. Community Service

"festival of the sparkling water," when singing, dancing and colorful pageantry take place on a fifteen-hundred-foot stage built on coal barges and anchored in the river. Detroit's annual Aquatic Day at Belle Isle brings out throngs of merry-makers. The city has cut miles of miniature canals on this island so that people may go boating in safety. Some of the attractions at a recent water carnival in Brockton, Massachusetts, were a game of water baseball between the city fire department and the city officials, a miniature boat race open to toy craft owned both by boys and girls, and a bathing suit style show.

Cities Teach Swimming

Cities are assuring the widest use and enjoyment of their water sport facilities by teaching boys and girls how to swim at an early age. They are also teaching swimming to adults who have not had a chance to learn. City-wide Learn-to-Swim Week every year prepare thousands of new swimmers for sport in the water. It is an asset to a city to have a swimming population. Not only does it mean conservation of life, but it means better general health through better general bodily development. When dwellers among crowded streets seek a cool plunge they are not thinking, as a rule, about the health they are acquiring. They are thinking about having a good time. To give them a good time is the immediate reason why cities spend money on swimming facilities. But, watching their boys and girls grow deep-chested and muscular, cities know that they are going to reap returns tomorrow in sturdier citizens.

Fine Water Supply for Jerusalem

During the five years of the English occupation and Zionist activity in Palestine more has been done probably to furnish the inhabitants of Jerusalem with a safe and adequate water supply than was done during the centuries of Turkish occupation says the *New York Times*. The city had but one small fountain, so that in former times the people were almost entirely dependent upon cisterns, which were oftentimes so foul that outbreaks of typhoid or malaria were common.

The military administration under General Allenby soon discovered strong springs in the Judean Hills south of Bethlehem, about seven miles south of Jerusalem, and by building a reservoir on a neighboring hill pump the water into this and then have it flow into Jerusalem by gravity.

But the long, dry summer proved too heavy a tax upon even this supply, so that the engineers of the Public Works Department turned their attention to three great reservoirs a few miles south of Bethlehem, known as Solomon's Pools.

These pools had been out of repair several hundred years. Two have now been cleaned and re cemented, and with their large supply are ready to increase greatly the supply of Jerusalem. The source of these pools is three miles further south and for half of this distance the water is brought through a tunnel cut through rock.

When the third pool is completed the capacity of the three will be forty million gallons, equal to the three months supply of water for the entire city.

Public Health in the Sixty-Seventh Congress

By JAMES A. TOBEY, M.S., LL.B., ADMINISTRATIVE SECRETARY, NATIONAL HEALTH COUNCIL, NEW YORK CITY.

THE Sixty-seventh Congress, which recently adjourned, is said to have made history in a number of respects. This Congress was the first which has ever held four sessions; it had the first woman senator; it gave birth to the bloc movement; and did a number of other striking things which have been sufficiently enumerated in the public press. This Congress added nearly a thousand new laws to the statute books, but only about 3 per cent of this number dealt with public health. Here, then, was a real opportunity for it to have made worth while history by giving adequate attention to the Nation's health, an opportunity which was passed by. Congress convened in special session on April 11, 1921, and adjourned on March 4, 1923. During this period it was in almost continuous session except for short recesses from time to time. In the four sessions, more than 21,000 bills and resolutions were introduced in both branches of Congress although, of course, many of these were duplicates: Of these bills 16,700 originated in the house and 5,419 in the senate. Of this number, 931 became laws and of these, 276 were of a private character so that 655 public laws were the result of the efforts of Congress.

In order to supply sanitarians with prompt, accurate, and impartial information on the public health measures before Congress, the National Health Council decided soon after it began operations in January, 1921, to issue bi-weekly bulletins on national health legislation. During the Sixty-seventh Congress, forty-five such bulletins were issued from the Washington office. They have listed approximately 350 bills and resolutions as being of direct interest to sanitarians. This number, however, represents only between 1 and 2 per cent of all the measures which were before Congress. Of the 931 laws which were placed on the statute books only thirty-one, not including appropriation bills, have a direct bearing on public health and some of these are purely local in character. Thus, only 3.3 per cent of the laws passed by Congress in the course of nearly two years have dealt with this important subject.

The health bills which did pass include the following public laws:—

No. 47. Veteran's Bureau created. August 9, 1921. (H. R. 6611).

No. 51. Packers Act. Regulating interstate and foreign commerce in live stock and dairy products. (H. R. 6320).

No. 74. Cincinnati Health Exposition, cancellation stamp for. October 10, 1921. (H. R. 8365).

No. 78. Veterans in Hospitals, tobacco for. October 14, 1921. (S. 1718).

No. 96. Anti-Beer act, supplement to national prohibition law. November 23, 1921. (H. R. 7294).

No. 97. Maternity and Infancy, promotion of welfare of (Sheppard-Towner Law). November 23, 1921. (S. 1039).

No. 110. Searcy hospital for colored insane in Alabama, land for. November 5, 1921. (H. R. 6961).

No. 125. Water supply for Fort Monroe. (H. R. 7204).

No. 129. Medical and surgical supplies transferred by Army to Russian relief. January 19, 1922. (S. 2708).

No. 194, No. 216, and No. 273. Hospitals for veterans. April 14, 1922; May, 1922; July 1, 1922. (H. R. 10864, H. R. 11547, H. R. 11588, resp.).

No. 227. Narcotics prohibited from importation or exportation except for medicinal purposes. May 26, 1922. (H. R. 2193).

No. 225. Pay of Army, Navy, Public Health Service, etc. (H. R. 10972), June 7, 1922.

No. 318. Tariff act. September 21, 1922. (H. R. 7456).

No. 330. Leprosy station in Hawaii. June 19, 1922. (H. R. 11589).

No. 347. Coal commission. (H. R. 12377).

No. 352. Fees, surgeons of Pension Bureau. September 22, 1922. (S. 3540).

No. 430. Federal Leprosarium, additional buildings for. February, 1923. (S. 3721).

No. 460. War Risk Insurance, amendment concerning. March 2, 1923. (H. R. 10003).

No. 463. Hospital in Arkansas, transfer. March 2, 1923. (H. R. 12751).

No. 472. Sewage drain at Miami, Florida. March 2, 1923. (H. R. 13272).

No. 513. Filled Milk, prohibition of in interstate commerce. March 3, 1923. (H. R. 8026).

No. 516. Reclassification of Government Positions and salaries. March 3, 1923. (H. R. 8928).

No. 519. Butter, standard for. March 3, 1921. (H. R. 12052).

No. 542. War Risk Insurance, amendment concerning. March 3, 1923. (H. R. 14401).

No. 536. Compensation for injured government employees. March 3, 1923. (H. R. 14222).

And the following Public resolutions:—

No. 63. Disposal of articles produced by patients of Veteran's Bureau. (H. J. Res. 313).

No. 65. Pollution of Navigable Waters convention. (H. J. Res. 297). August, 1922.

No. 75. Water supply of Kansas City, Missouri and Kansas. (S. J. Res. 216).

No. 96. Narcotic control, international cooperation in. March 2, 1923. (H. J. Res. 453).

While it is difficult to select the most important of these laws, there are a number which stand out as of real influence on national health. These include the Maternity and Infancy Law, popularly known as the Sheppard-Towner Act, the Filled Milk Law, the Hospitalization for Veterans, the Narcotic Act, the Anti-Beer legislation, and the measures which serve to increase the pay of Government health workers. The Federal Maternity and Infancy Act which became a law in November, 1921, has already been contested and is before the United States Supreme Court for a decision as to its constitutionality. This cause was brought by the Commonwealth of Massachusetts in accordance with a legislative resolution. Another suit was brought in the courts of the District of Columbia by a citizen of the state of Massachusetts, but both the Supreme Court and Court of Appeals of the District have upheld the law and the case has been appealed direct to the U. S. Supreme Court, where it will probably be tried with the one now pending.

The Sheppard-Towner act authorizes an appropriation of \$480,000 for the fiscal year ending June 30, 1922 and \$240,000 annually for five years thereafter, to be apportioned equally among the states. In addition, an appropriation of one million dollars for the fiscal year 1922 and a like annual sum for five years is authorized, this latter amount to be apportioned five thousand dollars to each state, and the balance according to population. In order to receive this sum, the state must appropriate an equal amount. The state must also accept the provisions of the act, authorize a state agency to administer it, and submit detailed plans, which must be approved by a Federal Board of Maternity and Infant Hygiene before the grant will be made to the state. The Children's Bureau of the Department of Labor is charged with the administration of the act and is given not to exceed 5 per cent of the appropriation for such purposes. A certificate of allotment of money to a state may be withheld by the Children's Bureau, with the approval of the board, but the state agency may appeal directly

to the President. The board is made up of the Chief of the Children's Bureau, the Surgeon General of the United States Public Health Service, and the United States Commissioner of Education. Already thirty-nine states have accepted the act of legislative enactment and legislation is pending in three others. Maine, Massachusetts, Louisiana, New York, Rhode Island and Vermont refused to accept the act.

The so called "Filled Milk" law would prohibit the shipment in interstate commerce of filled milk, which is described in the bill as an adulterated article of food injurious to public health, the sale of which constitutes a fraud on the public. This filled milk is further described to be any milk, cream, or skimmed milk, whether or not condensed, evaporated, concentrated, powdered or desiccated, to which has been added or blended any fat or oil other than milk fat. The law does, however, exempt certain products which are prescribed for infant feeding by a physician. At the hearings on this bill there was a good deal of conflicting testimony as to the nutritive value of filled milk, some eminent scientists holding that it was lacking in vitamins, while others asserted with equal assurance that it was wholesome and nutritious. The law does not, of course, affect the sale of such filled milk within a state, but already a number of states, including Utah, Maryland, Florida, California, Colorado, Connecticut and Oregon have laws either suppressing it or making the sale of it impractical, and similar laws are pending before the legislatures of other states.*

The Narcotic law (No. 227) amends existing law and creates a Federal Narcotics Control Board, to be composed of the Secretary of State, Secretary of the Treasury, and the Secretary of Commerce. This board shall determine the amount of crude opium and cocoa leaves which may be imported into this country for medicinal purposes. It is made unlawful to bring these drugs in except for these reasons and the law imposes a fine of not more than five thousand dollars and imprisonment for not over ten years for conviction of the offense and also sets out methods of seizure and procedure when drugs are imported. Another law regarding narcotics was the resolution requesting the President to urge upon the governments of certain nations the necessity for limiting immediately the pro-

duction of habit forming narcotic drugs and the raw materials from which they are made, to the amount actually required for strictly scientific purposes.

The United States Veterans' Bureau was created during the first session of the Sixty-seventh Congress and served to coordinate all medical activities undertaken on behalf of ex-service men. During this calendar year the bureau will disburse the stupendous sum of \$475,000,000. A number of appropriations for hospitals for veterans were passed, including one of seventeen million dollars which is an addition to the eighteen million dollars provided by the Sixty-sixth Congress.

The pay of officers of the Army, Navy, and Public Health Service was materially increased by a law which was signed in June, 1922, while the salaries of other Government sanitarians will be affected by the reclassification law, which passed during the last days of the fourth session. The senate held this reclassification bill for fourteen months after the house had passed it, and then completely rewrote the bill. Rather than lose the reclassification entirely, the house concurred in the senate amendments. Most sanitarians would come under the professional and subprofessional services in which annual salaries range from \$1,860 to \$7,500 and \$900 to \$3,000, respectively. This law goes into operation on July 1, 1924.

The control of leprosy was given greater facilities by the passage of the act appropriating \$650,000 for the new buildings for the Federal Leprosarium at Carville, Louisiana. The tariff act of 1922 contained a number of items of interest to sanitarians, principally with regard to duties on chemicals and drugs. The so-called anti-beer act, which prohibited prescription of beer by physicians aroused much comment and opposition from the medical profession, but became a law nevertheless.

Since only thirty-one health bills became laws, about 320 failed of passage. Many of these were minor measures—some of them "freak" ones—and a large number never got out of committee. Among the more important health bills which did not pass may be mentioned: the resolutions to amend the Constitution relative to restriction of child labor; transfer of the activities of the Interdepartmental Social Hygiene Board to the Department of Justice; the Fess-Capper bill for Federal aid to physical education; commissions for sanitary engineers in the U. S. Public Health Service; reorganization of the U. S. Public

Health Service; the uniform marriage and divorce bill; sale of Marine Hospital at Detroit; a number of bills relating to tuberculosis; and a couple of anti-vivisection measures. The District of Columbia, for which Congress legislates, fared particularly badly with respect to health measures, as bills to regulate milk, venereal diseases, optometry, and child welfare were not acted upon.

A plan for reorganization of the Federal executive departments was submitted to Congress by the President on February 15th, though no bill was introduced and no action taken. The principal matter of interest to sanitarians is, of course, the proposed new Department of Education and Welfare.

Existing bureaus which would be transferred to this Department of Education and Welfare are as follows:

(a) From the Department of the Interior—Bureau of Education, Indian Schools, Howard University, St. Elizabeth's Hospital, Freedmen's Hospital, Bureau of Pensions; (b) from the Department of Labor—Women's Bureau, Children's Bureau; (c) from the Treasury Department—U. S. Public Health Service; (d) from the War Department—Soldiers' Home; (e) from the Department of Justice—Office of Superintendent of Prisons; (f) independent establishments—Smithsonian Institution, Federal Board of Vocational Education, National Home of Disabled Volunteer Soldiers, Columbian Institution for the Deaf, and Veteran's Bureau.

The department would have four divisions, namely:—Health, Education, Social Service, and Veteran Relief, each under an assistant secretary. Other recommendations of general interest include the combining of the War and Navy Departments into a new Department of National Defense; transfer of public works activities from War and Navy to other departments, chiefly the Interior; change of name of Post Office Department to Department of Communications; and removal of non-fiscal services from the Treasury Department.

The Sixty-eighth Congress will convene the first Monday in December of 1923, provided no special session is called in the meantime. It is said that the President, having undergone the Sixty-seventh Congress, has no desire to assemble the Sixty-eighth before its time. This latter body will have the usual opportunity to pass much needed health legislation. Whether it will take the usual course and pass over most of it, or take an unusual course and pass it, remains to be seen.

*Editor's Note.—An appraisal of the filled milk bill as health legislation appears on page 352 of this issue of THE NATION'S HEALTH.

Legislation on Filled Milk

IN VIEW of the very regrettable action of Congress in passing the filled milk bill to which reference is made in another column of this issue of *THE NATION'S HEALTH* we desire to reprint with our own full endorsement an editorial in regard to this problem from the April issue of *The American Journal of Public Health*:

There is at present before Congress a bill prohibiting the shipment of filled milk in interstate or foreign commerce, declaring it to be an "adulterated article of food, injurious to public health, and a fraud upon the public." This bill has already passed the House and gone to the Senate accompanied by a report recommending the bill with slight changes.

Filled milk is a compound made up of skimmed milk to which 3 or 4 per cent of cocoanut oil is added. It is then condensed to approximately one-half of its bulk.

Our interest in this bill lies in the effect of such a compound on the public health. Both sides are represented by legal counsel, and the hearings before sub-committees have been characterized by controversies which are not at all scientific, and which indicate that public health is one of the least considerations involved. It is charged that the whole matter is a trade fight between two large milk companies, one of which is putting out filled milk, in addition to its other business, and it is almost impossible to read the transcript of these hearings without gaining the impression that this is a fact.

As far as the injury to public health liable to be done by filled milk is concerned, the discussion centers largely around the vitamins and particularly fat soluble "A." In the report made to the Senate it is stated that "even tuberculosis may be traced to lack of vitamins in the diet." In view of such statements one can hardly deny the charges made that there is a great deal of "vitamin hysteria" at the present time.

Needless to say, women have taken part on both sides and some of the most untenable statements are made by them. One who qualifies as a nutrition expert, employed by the Dairyman's League Cooperative Association, says: "We are not measuring our food in calories any more." "You don't want any more heat on a day like this." Another, speaking of a certain brand of filled milk, says: "Yet this is but fifteen or twenty cents worth of poison." Even some of the physicians who qualify as experts make untenable statements. Certainly hearings before committees are not places in which to get scientific facts, although the discussions are often interesting and illuminating.

Certain dairymen's associations are supporting the law. As far as the dairy trade goes, we are only incidentally interested, but it is well to remember that in the past, laws protecting the dairymen have not usually been made with much regard for the public. The bill which taxes oleomar-

garin, and puts a prohibitive tax of ten cents a pound on colored oleomargarin, is still in force, though nothing can be said against oleomargarin from the public health standpoint. On the other hand, butter makers universally color butter, and it is taught in the agricultural colleges throughout the United States. The addition of one or two mills worth of artificial color adds nothing to the nutritive value of butter, yet it makes a product which is unsalable as butter, or at best salable at low prices, sell to the consumer at the price of good butter. Just why this should not be considered a fraud is not easy to say, but it is sanctioned by the law of our land in the interests of the dairymen.

Our Government also insists on the misbranding of the vegetable fat butter substitutes as oleomargarin, though they bear no relation to that product further than the fact that they are substitutes for butter. It also sanctions the sale of renovated butter, than which there are few more repulsive articles of food.

Considering this matter from the public health standpoint, we admit without discussion that the normal milk of any animal is a perfect food for the young of that species; that some sort of milk is the best substitute for human milk, though cow's milk is very far from being a perfect food for infants; that cow's milk is perhaps the best source of vitamin "A," and that this is contained largely in the fat content. The experiments of Hess indicate that skimmed milk can furnish nutriment for infants over long periods of time, and the conclusion either that vitamin "A" is not as necessary for these infants as experiments on rats seem to indicate, or else that skimmed milk contains a considerable proportion of this vitamin seems to be justified. In testimony before the subcommittee Dr. McCollum has laid great stress on the fact that as a nation we are undernourished. Referring to faulty bone development, as pointed out by Hess, defective teeth and lack of normal weight, he at least indicates that these are due to lack of vitamin "A," since they are used as arguments against filled milk. His own experiments indicate that skimmed milk contains about one-half the vitamin "A" that whole milk does, or in other words, that the butter fat contains about 50 per cent of vitamin "A," and the other portion of the milk 50 per cent, so that from the public health standpoint, as presented by the proponents of this bill, the whole fight is over 50 per cent of vitamin "A."

It is hard to understand just why the dairymen have become involved in this fight, since it opens up a new and advantageous market for skimmed milk. Skimmed milk is a valuable food, corresponding in its value closely to lean meat. It contains all the protein and has a high caloric value. The waste of skim milk in this country is a crime. The Department of Agriculture* estimates that the amount of skimmed milk represents annually a protein value of 913,000,000 pounds,

approximately equivalent to eight billion pounds of beef, which is said to be nearly equal the annual consumption of beef in this country.

A large amount of this goes into the making of paints, billiard and pool balls, buttons, brush backs, etc.² Dr. Carlson, of Chicago, points out very properly that the waste of all this food material is a very serious public health problem, in which everyone will agree who studies the question.

If filled milk is sold as whole milk—and we are quite ready to admit that this occurs sometimes—it is a matter which should be dealt with as a fraud just as are other food adulterations. From the testimony given by some of the investigators, who dressed a girl in poor clothing and sent her around to various groceries, it would not seem hard to collect the evidence.

The public should not be deprived of this valuable food product, which is digestible and nutritious although not a complete food, because in some instances such a product is sold as whole milk. Cheese made from skimmed milk or partially skimmed milk is extensively used as a diet in various parts of the world. In the United States cheese is not used as a substitute for meat as much as it should be. The skimmed milk which now goes for manufacturing various articles might well be made into skimmed milk cheese and sold to the vast number of people in the United States who need a cheap source of protein. It would be just as rational to exclude from interstate trade all of the vegetable oils, cotton seed, peanut, corn, and cocoanut oil, as it would be to condemn a condensed milk in which the butter fat was replaced by these vegetable oils. Many of the shortening and cooking compounds are made from the vegetable oils, and have been used for years without any detriment to the public health as far as the evidence shown.

We are in full sympathy with the dairy interests of the United States, and have repeatedly urged the more extensive use of milk and will continue to do so. We have no sympathy with the sale of oleomargarin as butter, nor the sale of filled milk as whole milk, but as said before, most states have machinery for dealing with such frauds. Even when whole milk is bought the cream is sometimes removed and the skimmed milk used as food. If all food stuffs in the manufacture and sale of which frauds have been or can be committed were excluded from trade, there would be a decided food shortage, and milk itself would be among the first to be debarred, since there are few articles which have been more adulterated, and none which require more constant attention from inspectors and health officials.

The original bill excluded from interstate trade such preparations as Dr. Gerstenberger's "S. A. M." Since it has been demonstrated that this is an excellent substitute for milk, although it contains vegetable fats and cod liver oil, a compromise has been effected so that this compound will be admitted to trade.

1. Testimony of Prof. E. E. Asgar, page 148.

2. The production of dried casein was 20,000,000 pounds in 1922.

It has not been shown by anyone that there exists in this country a vitamin "A" starvation, nor has it been shown that the sale of filled milks and butter substitutes has increased the malnutrition of our people. It is admitted by all that whole milk varies in its value according to the food of the cow, and that babies

nursing from their own mothers frequently suffer from some of the deficiency diseases due to the poor quality of the milk. With these facts in mind is it wise or just to prohibit the sale of filled milk, because of its deficiency in vitamin "A"? Certainly the public health argument has no standing in the case.

of which in the past is believed to have been the most potent engineering factor in reducing the typhoid and the general death rate.

At the present moment the water-supply engineer is often in a quandary as to how much additional expenditure he is warranted in recommending for one supply instead of another on the possible chance that a few thousand or hundred thousand or millions of dollars—according to the size of the city—thus spent will provide water that will lessen by a shade a typhoid rate almost at the vanishing point or perchance in some way which no one can clearly and positively define reduce some other human ill. The engineer, the health officer, the city councilman and the taxpayer, each and all, need a more delicate and certain index than is available, now typhoid has been reduced to so low a figure, of the causes of the past decline in typhoid and the probable cause of future decline. Have the engineer and the health officer come to the bottom of the curve so far as efforts against typhoid in many of our cities are concerned? Can the experts hereafter merely hold what they have already gained? If further reduction may be expected, and typhoid wholly eliminated, then by what means? Would the same, or perchance much less expenditure, capital and operating, reduce by two or by five per hundred thousand the death rate from some of the causes other than typhoid as against a half or a tenth on the typhoid scale? Similar questions are pertinent as to larger expenditures than are considered wise by most sewage-works engineers.

Adolph Lewisohn, president, and Hugh Frayne, vice-president, of the National Committee on Prisons and Prison Labor have offered the cooperation of their committee in investigating the evils of convict leasing. Their letter to Governor Hardee of Florida mentions their possession of the facts in the turpentine situation as one of the worst abuses in the country today. Abolishing the leasing system, they say, would accomplish little in eradicating abuses if convicts are left idle; hence the necessity of a study of every ramification of the situation, such study to be done under state supervision. Such a scientific study should evolve a constructive penal system, it is held.

Cleveland reports its garbage reduction has been self-sustaining for all but two years and shows a big profit from its by-products.

Engineering and Public Health

UNDER the above title M. N. Baker, associate editor of the *Engineering News-Record* delivered one of the DeLamar Lectures in Hygiene before the Johns Hopkins University School of Hygiene and Public Health on November 20, 1922. This was repeated with slight revision before the Sanitary Section, Boston Society of Civil Engineers, March 7, 1923.

Extracts from Mr. Baker's address follow: Engineering is the art and science of planning and doing a given task as well as it needs to be done at the least cost consistent with that end. Such a definition involves a clear idea of the aims of every endeavor, the best but least costly means of attaining those ends, and the faculty of discerning the point of diminishing returns. The latter is of great importance in view of the vast amount of engineering work still undone and that must await doing because of lack of money. Let me make this point clearer. In every city there are numerous public improvements and public services constantly making their demand upon the municipal treasury. If each demand were satisfied ideally the total cost would bankrupt the city and the taxpayer alike. Each improvement or service must therefore be considered in the light of its relative importance and take its place accordingly in a far-looking municipal program—something all too rare in American municipal life.

Returning now to the point of diminishing returns in the field of public health work: Public funds being limited, so must be the pursuit of the ideal in each branch of public-health work in order to achieve the largest possible total gain in saving of lives and sickness. The highest ideals in water supply, for instance, should be postponed when additional expense for further improvement will have no probably measurable effect on typhoid or the general death rate and while there is every reason to believe that the money needed to make the water supply ideal would, if expended on the milk supply, effect a notable reduc-

tion in tuberculosis and infant mortality. A more striking illustration would be the concentration of health department effort on garbage disposal, as is so often the case, while no really efficient work is being done to control communicable diseases or reduce infant mortality.

House and building design and construction, with particular reference to air, warmth and light, dryness, the saving of labor for housewives, and general convenience play their part in public health. Heretofore, these things have been regarded as the function of the architect, but for years now we have had heating and ventilating engineers, while in various ways the engineer is becoming more and more concerned with the construction of houses and other buildings. From the engineer we may expect a reduction in the cost of housing that can come only from saving labor and material through systemization, quantity production and like engineering methods. With a reduction in the cost of shelter may be expected a relief from the overcrowding and other evils that undermine health and spread disease. This brings us to housing in its broader aspects, of which no more need be said than that it is a part of the new science of city planning, including zoning, which after so many long years of unfortunate and shameful neglect is now beginning to receive some part of the attention which it so richly deserves.

I believe it is to city planning and its results that we must look for much of the future improvement in public health and particularly for a further reduction in the general death rate in so far as these depend upon engineering work, a reduction traceable not so much to any one readily specified measure as to improvement in many inter-related causes that go to make up community convenience, comfort and mental and physical health . . .

For many years past the engineer measured the results of his efforts in the sanitary field by the typhoid death rate. At least this was true as regards water supply, the improvement

Douglass Park at Indianapolis

By R. WALTER JARVIS, SUPERINTENDENT OF PARKS, AND RECREATION, INDIANAPOLIS, IND.

REALIZING that a large area of unoccupied ground was located in a growing neighborhood the Board of Park Commissioners of Indianapolis exercised every effort in order to acquire it for park purposes where people from all classes and all denominations could come for recreational privileges. Although the major part of the neighborhood was made up of the colored people the inhabitants of the entire section were welcome. It was thought best in planning the park to place the play-

all times. The men were especially pleased because lighted horse-shoe courts were provided for them. One of the largest and finest swimming pools of the middle west has been placed at the extreme north and arrangements have been made for all ages to participate in this type of recreation.

The complete pool cost \$70,000 and has an area of twenty thousand square feet. It is so constructed that 70 per cent of water area is outside of guard rope and has a maximum

one period of the day one end of the pool may be reserved for women only, leaving the other section for men. One section can be made shallow for smaller children. The pleasure part is taken care of by four chutes which are continually flushed by flowing water, two swings, 2 high dives, two guard ropes and two revolving rafts. Sixteen hundred lockers are provided for swimmers at any time—that means sixteen hundred can enjoy the pleasure of the pool at the same time.

The colored Y. M. C. A. has be-

This swimming pool at Douglass Park has dressing rooms below the raised walk.

grounds at the extreme east end which rose to a high hill. Every kind of apparatus available was placed on this playground; slides, swings for all ages, merry-go-rounds, maypoles, etc. Since the greater number of people were colored it was thought advisable to place colored instructors and matrons on the ground to supervise the work. In order to prepare for the adult attendance splendid tennis courts and two baseball diamonds were planned and well taken care of at

depth of 9 feet. Care was taken so that 85 per cent of the pool area is wadable and not over 5 feet in depth. This means that only 15 per cent of the area of pool is too deep for an ordinary person to wade in and the entire pool deep enough for swimming. One advantage of the shape of the pool is that the area of deep water is cut down thereby reducing volume of water needed to fill it. Another great advantage of the pool is that waders can be segregated, that is, at

come so enthusiastic over the work that is being done that special arrangements have been made by which all the boys who care to may be taught swimming free of charge.

We realized in opening Douglass Park that recreation is by far the quickest approach to any man's heart. We also understood that the people in this section were very religious and anxious to learn, but like all other citizens in Indianapolis they were desirous for recreation. The keen de-

Recreational activities at Douglass Park are supervised by colored instructors and a colored matron. Adult attendance is encouraged by the management as well as play for children.

The playgrounds are placed at the extreme east end of Douglass Park. Slides, swings for all ages, merry-go-rounds, Maypoles,—every kind of recreational apparatus is made available to the whole population.

sire in the past of the colored people for recreational centers has been demonstrated by the fine way in which they have appreciated the park and school grounds which were provided for them in Indianapolis. Douglass Park which opened for the first time during the summer of 1921, and its complete pool in 1922, is sufficient

proof that the colored folks of our city are ready and waiting for recreational opportunities. The colleges and state schools for colored people are realizing the need for trained colored workers in this field and have provided excellent courses in recreational subjects. As these trained workers instruct the people at Douglass Park

they will teach their people a keener appreciation for the need of play, play spaces, and play facilities. During 1921 and 1922 Douglass Park truly became the pivot around which all amateur athletics revolved as well as the fountain of inspiration for organized play among the younger children.

European Council for Nursing Education

BY KATHERINE M. OLMSTED, DIRECTOR, PUBLIC HEALTH NURSING, LEAGUE OF RED CROSS SOCIETIES, PARIS, FRANCE.

THE European Council for Nursing Education held its second annual meeting at the headquarters of the League of Red Cross Societies, Paris, March 12-16, 1923. About three hundred nurses from eighteen different countries attended the conference.

It was not just the interest of the special papers and the individual speakers nor even the great pleasure and satisfaction of having an opportunity to meet and become acquainted with nurses from so many countries that made this recent meeting in Paris unique and different from all other nursing conventions the author has ever attended. The spirit of unanimity and the definitely recognized interdependence of nurses and those interested in promoting nursing education was the greatest contribution this meeting gave.

As never before it was acknowledged that the interests of a group of nurses in one country are really not separate from those of any other country and that in discussing nursing education; persons not themselves nurses, often have ideas, suggestions, and plans well worth listening to and often worthy of adopting even by nurses.

Not less important was the value of having hospital administrators, Red Cross officials, doctors and persons actually responsible for the education of nurses and in some countries the lack of education, hear the many very excellent papers and discussions read by nurses who are successfully administering training schools in near by countries.

No one who attended this meeting called by nurses and conducted by nurses would question their wisdom in opening all but the business meetings freely to everyone interested in nursing if they could have seen and listened to the many earnest conversations, on all sides, heads and tongues were busy and many of us overheard remarks such as "well if they can do

that in—we can do it in—," "We can have a longer course just as well as not." "We too must have a modern central school building." In one country, where nursing standards have always been at very low level and no one at all interested in helping a few struggling nurses to improve it, a most influential and well informed woman has returned with the determination she says "to have some thing worth while for our nurses to tell about at the next conference." The conference demonstrated convincingly that we need this means of thinking together, and further that we need the benefit of joint judgment and free open debate upon our nursing problems. Just as each group is profoundly affected by the seriousness of the nursing questions arising in its own country, so it is the direct responsibility of each to help to solve them.

The European Council for Nursing Education is scarcely a year old, born only last June in Prague, it has scarcely had time to formulate its policies and as its president, Miss Newton from Belgrade, aptly remarked "we thought we had a pigeon but we find we have an ostrich." All plans are made for a small group of nurses to discuss comfortably their problems together but the spirit which brought so many nurses from countries advanced in nursing and so many advanced thinkers from countries considered very backward in nursing is a spirit and a force which cannot be dealt with easily nor carelessly.

The remarkable interest and enthusiasm of all those attending the conference gave life to a new organization and plans are being made and methods being studied in order to successfully adapt this organization to meet the needs for future work.

In the minds of many of us are the questions: What shall be the future of this organization? And is there a need for such an organization and special work to which it should consecrate itself?

It is believed that the very near future will show us that it must enter upon a much broader program than was conceived in Prague last year by the few nurses who originated the Council and who met solely and selfishly for the purpose of discussing and gaining stimulation and new ideas for themselves from those similarly occupied in other countries. Much thought will undoubtedly be put into the formation of a suitable constitution for the council but the following aims expressed in the original are worthy of survival.

(1) The further attainment of uniformly high standards in schools of nursing which are being established in Europe.

(2) The initiation of a campaign of education destined to inform the public as to: (a) The standards requisite for a fundamental education in nursing. (b) The position which the nurse should occupy in the community after her graduation.

(3) The establishment of a simple organization which will serve the nurses until such times as they are able to form their own national association and become members of the International Council of Nurses.

It has been said that successful conferences are dependent upon certain elements, of which several important ones are, leadership, the development of membership and presentation of concrete problems for solution.

Before the first few days of the meeting were finished several leaders became recognized; the first and most generally acknowledged was Baroness Mannerheim. Had we not known that she represented as president, the International Council of Nurses, had we never heard of her magnificent work for nurses in Finland and throughout the Scandinavian countries, she would still have stood forth as a leader. Distinguished above others by efficiency, strength, wisdom and a sense that she was filled with human sym-

pathetic feeling and understanding that endeared her to all. Miss Enid Newton the new president of the European Council for Nursing Education gained the admiration and respect of all by her frankness, her fairness, her tact, and her ability to look beyond the harassing problems of the week in the clear and promising future of the Council. Her strong personality and her sense of humor won all our hearts.

Membership was eagerly sought and many applications were received but, owing to the necessity of making certain changes if possible to formulate an organization coincident with and in cooperation with the International Council of Nurses, no action will be taken immediately upon membership applications received.

A great many concrete problems for solution were presented and ranged from the problems of the schoolroom to those of an organization best fitted to allow fair open discussions on all the vexed questions.

Perhaps this organization will never make a greater contribution to nursing than to have crystallized this vague group consciousness. It may well serve during these uncertain times as the medium through which we who are interested in nursing can think and work together. It has already been a clearing house for our ideas and a forerunner of our discussions. In our enquiry as to the apparent and special need for this organization let us first consider its particular make-up.

It holds a unique position as a voluntary body of the workers in the field, democratically organized and representative of all parts of Europe, all varied types of nurses; it exists alike for all, to serve each and any group in so far as its funds and its policies which should be passed upon by all, permit.

In other words, here is the official body, representing experts working in the field of nursing, to be consulted by all and developing itself to provide a particular service that will benefit all groups interested in nursing.

At present there is in Europe no other organization of this type to which individual nurses or people interested in nursing can belong.

The International Council of Nurses is a goal toward which organized nursing councils in countries advanced in nursing can and should aspire but it is to the European Council that nurses and individuals struggling toward developing nursing in its infancy, can turn for encouragement and help. The members are for the

most part pioneers in nursing in countries where there are few nurses and no national organization where nursing standards depend not upon legislation or public opinion but upon the initiative, the intelligence and the fortitude of perhaps but a few people.

It is to these people, some of whom are nurses, others Red Cross workers, physicians, health, educational, or government authorities, but all advocates of nursing standards, high or low, that the European Council for Nursing Education can best fulfil the task it has set itself to do.

New Health Officer for New Haven

Dr. John L. Rice has been appointed to fill the vacancy caused by the death of Dr. F. W. Wright who was health officer for the New Haven, Conn., Department of Health for many years.

Dr. Rice, a native of Connecticut is a man of excellent training and wide

Dr. John L. Rice, health officer appointed to fill vacancy caused by the death of Dr. F. W. Wright.

experience. He graduated from Wesleyan University in 1912; worked as a physiological chemist for a time at the Sheffield Scientific School, Yale University, and then went to the Syracuse City Health Department and Syracuse Medical School. In 1913 Dr. Rice resigned as assistant city bacteriologist of Ottawa, Canada, to take up the study of medicine at the Johns Hopkins Medical School. During his medical studies he participated in rural sanitation work carried on by the Maryland State Board of Health and the U. S. Public Health Service.

After receiving his medical degree he served as bacteriologist at the Roosevelt Hospital, New York, and

then went into the employ of the International Health Board. In this service he gained experience in many phases of public health work in Costa Rica, Guatemala, and Panama. In 1919-1920 Dr. Rice was city and county health officer, Maysville and Mason County, Kentucky, cooperating in the programs of the State Board of Health and the International Health Board. After acting as sanitary supervisor of New York state for a year Dr. Rice returned to the International Health Board work at Trinidad and in Porto Rico.

Frank W. Wright, M.D.

News of the death of Dr. Frank W. Wright, health officer of New Haven, Connecticut, for nearly a quarter of a century, has been received with regret by many workers in the field of public health. Dr. Wright was taken ill while visiting his son, Dr. L. H. Wright of Palmer, Massachusetts, and died two weeks later at the age of sixty-eight.

Dr. Wright was for many years a member of the American Public Health Association and at the last meeting in Cleveland became a Charter Fellow. His long and faithful service made him a figure of note in his community and his kindly personality endeared him to all who knew him.

Causes of Lost Time Accidents

Sanford has analyzed the lost time accidents in a group of manufacturing plants having approximately 40,000 employees. (*Safety Engineering*, Feb., 1923, *xlvi*, 2.)

The causes are as follows:

Power transmission machinery.....	0.8%
Point of operation.....	10.3%
Handling material.....	30.7%
Falling material.....	5.5%
Flying chips, emery or other dust.....	11.0%

The author further states that during 19 months of war the battle casualties of the United States were 48,000. During 19 months that accidental fatalities in the U. S. were 126,000. Of the latter, 35,000 were industrial, 91,000 occurred in homes and streets, of which group 25,000 were children of school age killed on the streets.

More than one million youths took part in the hikes, games, and sports during Boy's Week in New York. The Rotary Club, athletic associations, Boy Scouts, Hebrew Association, and Woodcraft League were supported by activities in five hundred churches. More than one hundred industries took part in observing Boys' Day in Industry.

Health Work of Committee for Devastated France

IN THE winter of 1916-1917 the American Committee for Devastated France, then in its infancy, crossed the ocean on a mission vaguely understood but inspired by the belief that this group would express to the war sufferers in France the sympathy of the American people.

Work was started in the Department of the Aisne which had been recently evacuated by the German armies on their return to the Hindenburg line. In the spring of 1917 it became necessary to decide whether the relief should be spread over a wide area or limited to organized action in restricted locations. It was decided that the latter action was the only possible course to pursue if the communities were to become once more self-sustaining.

In the offensives of March and May of the same year the mission was evacuated and followed the refugees of its region into the interior. Yet it did not lose sight of those forced to remain behind in the war zone. When the inhabitants were allowed to return in the winter of 1918 the workers were already at their posts, in a scene of desolation even greater than it had been a year before.

In the winter of 1918-1919, following the signing of the armistice, the need for relief was greater than ever. Pouring into the country were many refugees, repatriated from Germany through Switzerland. Many of them, even after the shock of the disaster that had befallen their homes, refused to leave them and set their energies to the much needed work of reconstruction.

During the winter the workshop of

the committee was called upon to make many provisional shelters in order to keep the inhabitants alive. The confidence that the inhabitants had in the committee made it possible for the workers to stimulate among the repatriated French people the formation of agricultural syndicates, agricultural cooperatives, and building cooperative societies. Quantities of clothing, food, household furniture and utensils, garden tools and other necessities have been handled by the committee. This work was discontinued in a village as soon as the French tradesmen returned and started their business anew. Aid in building construction, agriculture, public health service, home visiting and assistance, library service, and stimulation of physical training and athletics, the boy scout program, and community activities have been continued in varying amounts as the needs of the situation seem to demand.

France suffered greatly during the war. The latest evaluation of damages to property due France from Germany is officially estimated at 102 billion francs. Damages to persons is estimated at an additional seventy-eight billion francs. The cost of the war to France in proportion to her national wealth was over four times as great as the cost to the United States. France lost nearly 18.5 per cent of her mobilized men between the ages of 18 and 45, or 11.88 per cent of her entire population. In addition she has nearly a million seriously disabled men. It is under such handicaps as these that the Committee has aided France in her attempt to reconstruct and rehabilitate her devastated areas.

Material reconstruction has advanced to such a stage that the Committee no longer considers it a primary responsibility though they still have left two definite services, the agricultural syndicates of Aisne and the workshop at Blérancourt.

The moral reconstruction is now the major responsibility. Public health, libraries, and certain foyer activities still need aid but will eventually be strong enough to become a definite part of the community life after the Committee has withdrawn. General social activities including children's work, the Blérancourt Hospital, recreation, education, etc., still offer opportunities for unlimited service.

The annual report of the Committee for the year ending March 31, 1922, contained the significant statement that "First in importance among the American Committee's activities is its public health work." The report continues, "This service, with its emphasis on child hygiene, maternity care and education, and district nursing, has been of inestimable value to thousands of families in the Aisne and Rheims, not alone for actual present needs, but in education along hygienic lines, and for the future of nursing of France. It is a contribution to French community and national life that America cannot leave to fend for itself, even after the American Committee withdraws."

During the year covered by this report twenty-five nurses, the majority of them French, were employed in the Aisne and at Rheims saving the small army of undernourished boys and girls in the region, finding practical means to assist the more ma-

American Committee nurses in the Aisne, France. In the foreground, Miss Evelyn T. Walker and Mrs. Mary Breckinridge, heads of the nursing service.

Soissons, the "Goutte de Lait." The number of carriages indicate that in spite of a down-pour of rain it is a busy day within. In the foreground Little Red Riding Hood going home with her milk.

Nurses starting out on morning calls.

This baby was born in a dugout at Vauxbuin.

ture, alleviating the sufferings of the aged, and caring for pregnant mothers and babies born to a most unequal struggle for existence.

The French government reported for the Aisne an infant mortality rate of eighty-seven per thousand, while for the same period the rate was thirty-five in the region under the care of the Committee's nurses. This rate is based on frequent local count vouched for by the local authorities.

Primitive living conditions still exist in the rural sections. The story of an epidemic of dysentery (*Shiga's bacillus*) in one of the communes during the summer of 1921 gives an idea of the difficulties under which the nurses are forced to labor. "Only one of all the families afflicted had any toilet facilities whatever; this situation the nurse met for each home by having a hole dug, lined with lime, and covered by a special lid made in the Committee workshop. Preventive serum was scarce, often obtainable only by the nurses' personal visits to the Pasteur Institute, sixty miles away. When enough was to be had, the nurse gave as many as seventy-eight hypodermics in a day—in all a total of seven hundred injections of serum were given in this village of eight hundred people."

When the inhabitants of Rheims returned they found their homes destroyed. They were obliged to build all around the city on the outskirts hundreds of little houses, grouped together, built on battle-fields, no drainage, no roads, no trees, nothing but desolation. It is in these quarters of Rheims that the nurses of the A.C.D.F. have been working.

Between April 1 and Oct. 1, 1922, seventeen nurses in the Aisne and eight in Rheims made a total of 44,310 home visits, and these under most adverse conditions in a district largely rural and with a population of seventy thousand. Dispensary visits during this period exceeded thirty thou-

sand. Service was maintained in 127 villages of the Aisne as well as in the town of Soissons.

The nursing service costs the committee fifty thousand francs a month.

From April 1, 1921, to April 1, 1922, twenty-five nurses of the service cared for 12,263 children's cases and 4,477 adult cases. About a third of these were dismissed at the end of the year. The full number of cases necessitated 157,174 visits; 63,364 at dispensaries, 86,596 at homes, and 7,214 at places of business. The summary of the year's work continues:

After a year and a half of intensive work by our nurses more than half of the children in our villages still need follow-up nursing. Of a total of 3,673 children examined during 1921-1922, there were 2,121 still requiring the attention of our nurses.

An analysis of the maladies revealed by examination shows 3,911 maladies of which 926 were cured by the end of the year, 2,439 improved and 492 unimproved—these last, as a rule, were cases refusing to submit to the necessary operative or other treatment.

This is a remarkable record, both

Off for a holiday in Switzerland.

of need and of service, for it represents an average of over 10 visits to each case.

Surgical dressings and treatments numbered 50,350 in the Aisne, and 56,915 in Rheims, a total of 107,265 during the year. Milk to the amount of 36,751 litres (about 9,702 gallons) was carried to babies and old people.

Baby clinics were held regularly in nearly all of the villages; 594 of these were held by French doctors in thirteen villages, and 1,169 by nurses in sixty-eight villages. Children in the village schools received thorough medical examination, the committee nurses doing the preliminary and follow-up work. Operations for tonsils and adenoids numbered 185 and 952 cases were taken to specialists.

During nine months dental clinics in thirty-two villages cared for 1,960 patients, mostly children. The committee held demonstration clinics at the American Red Cross Child Welfare Expositions at Douai, Camprai, and Valenciennes. These clinics cared for 6,814 children between the ages of four and fourteen.

One of the committee's nurses reported finding an eight or ten months old baby absolutely alone in a far-off barrack. The baby gazed wonderingly but unafraid at the face outside the locked window. When questioned about this discovery the patron of the farm said:

Mademoiselle, it terrifies me daily, because you see, fifty metres away, one of my workmen's barracks burned, a few weeks ago, while they were in the fields, they did not know how—suppose it had been the barrack with the baby! But what can I do? This woman's husband was one of my trusted farm-hands before the war, and when he returned a *mutilé*, I kept him on and let him do what he could. He died, poor fellow, a few months ago, and his wife works on the farm. She cannot take the baby with her and there is no one with whom to leave it. I cannot afford to let her stay in the barrack and not work. I cannot send her away because she has no dwelling to go to. Ah, Madame, if we only had some place where we

could have small children taken care of!

This need of the inhabitants was met by *garderies* or nurseries and by kindergartens. During the year covered in the last annual report 67 infants were cared for daily in nurseries and 344 older children in kindergartens.

In February, 1920, the Committee took over the unpretentious but finely equipped group of barracks at Blérancourt which had up to that time been administered by the American Women's Hospital Unit. Originally planned for only twenty-five beds this was the only hospital in the seventy miles from Soissons to St. Quentin. The number of beds was soon increased to forty and later a whole new ward for maternity cases was added. While in charge of the American Committee this hospital admitted 1531 men, women, and children and 319 babies were born there.

Before the war inhabitants of these rural districts had a horror of hospitals—to be sent to one meant an illness so serious that death was staring them in the face. Blérancourt hospital has given these people a new insight into the care of the sick. As hospital facilities in the Aïnse again became adequate and there was no possibility of the Blérancourt hospital being made permanent by the French authorities, it was closed on October 31, 1922.

Every month a group of delicate or convalescent children have been sent to Geneva. The expenses of the sojourn in Switzerland are met by the Swiss Committee; the traveling expenses from Soissons to Geneva and return are paid by the French Government; and the nursing service of the American Committee has to pay only such minor expenses as food for the journey, provide additional clothing for the children who must be equipped for a three months' stay. From the organization of this service in April, 1921, up to October, 1922, its benefits have been extended to 289 children and two adults. The average gain in

weight has been five pounds and gains as large as fifteen pounds have been recorded.

Not only are these children given the benefits of good physical and moral guardianship, but many have received special care for semi-chronic eye conditions, unusual orthopedic operations, and the like.

All the features of the health work of the American Committee for Devastated France can not here receive due treatment. Most of them are of a temporary nature and can in time be taken over by the French. One branch of the work, however, will for a longer period demand the aid and encouragement of the American Committee. This is the organization of a training school for nurses. In spite of the very enviable position that France holds in the field of medical science it

nursing service of the American Committee in the Aïnse and in the various hospitals with which they have been associated has demonstrated to France what can be accomplished by the intensive work of well trained nurses in a community, as well as the assistance that a high-class nurse can be to doctor and patient in both private and hospital practice. The work of American nurses during the war served also to arouse France to her need.

The American Committee was approached by a group of French doctors headed by Prof. Calmette of the Pasteur Institute, and by other influential citizens saying, "We want to do better; we shall do everything we can to help you, but we do not know how to organize a modern nurses' training school! Won't you help us so

that we may continue to do such work as you have been doing in the Department of the Aïnse?" If it had refused to listen and act the committee would have missed a great opportunity.

To secure properly trained nurses the committee had been forced to draw practically all of its personnel from the Bordeaux school of Dr. Hamilton. Paris leads France and if a really modern school could be established there

it would mean that similar schools would spring up all over the country.

The first thought, or course, was to find a general hospital in Paris to which such a school could be attached with advantage but the difficulties proved insurmountable. Private hospitals in the city were also found out of the question. In March, 1922, negotiations were started with Dr. Oberthur, of the Hospital of Auteuil. Dr. Oberthur has a private hospital of fifty-five beds, but his life dream has been to have one of about three hundred beds where the middle class could have, at a moderate price, proper medical and surgical care, with a certain proportion of absolutely free beds. As the prospects of realizing this dream materialized he began

A lesson in child hygiene—but the child objects.

is, in its nursing service, far behind almost any other nation.

With the exception of the Florence Nightingale school at Bordeaux, none of the French training schools for nurses would be accepted as such in America or England. The young woman who takes care of the sick in the public hospitals of France is of the ward-maid type. Her lack of education and professional training is horrifying to those who consider that the nursing profession should be composed of women of good education and high moral standards; it is unbearable to think of confiding to the care of the average French nurse one who is in need of skilled attention.

The medical profession realize the need of better trained nurses. The

to realize that a hospital of this kind ought also to have a modern nurses' training school attached to it. At the same time that Dr. Oberthur was looking for a training school the Franco-American Committee was looking for a hospital. Luckily fate brought these two bodies together. Dr. Oberthur now has at hand the money to build a 350-bed hospital embracing all branches of medicine and surgery necessary for the proper training of nurses. This hospital will be ready for occupancy in October, 1923. Two of the committee's nurses are now studying the administration

of training schools at Columbia that they may be of assistance in organizing the school.

Plans are also being considered for the formation of a new school in connection with the Rue Amyot School.

The American Committee for Devastated France is the only relief organization now working in the country. Its past accomplishment and opportunities for future assistance, particularly in the field of public health, justify its continued existence and reflect great credit on those who conceived and have admirably carried the program to its present stage.

13 hide handlers, including storing hides 8, lightering 2, carting 2, goat's wool 1; 9 hide scrapers; 8 handlers of raw hides; 4 wool combers, including sheeps' wool 2, horse hair 2; 4 wool packers; 3 workmen; 3 cutters; 3 sorters; 3 watermen; 2 weighers; 2 hide hangers; 2 day laborers; and 1 each of the following specialties; fleshier, peeler, stretcher, baler, carder, spinner, beater, skinner of washed wool, dryer of washed wool, worker in washed wool, warehouse foreman, director of works, dryhide worker, dry-hide warehouseman, warehouse inspector, lighter man, dockman, custom-house inspector and mechanic.

One hundred twelve were men and forty-five women; 37 were boys of less than eighteen years of age.

Of the total, 58 worked in goat skins, 51 with wool, 13 with sheep skins, 8 with dry hides, 5 with horsehair, 1 with goats' wool, 3 with cowhides, 6 with various unclassified hides. There were 19 in which the nature of the transmission was not precisely known.

Complete cure took place in 136 of those attacked, two were rendered permanently and partially incapacitated for work and 19 died, a mortality rate of 12 per cent.

These figures have been set forth *in extenso* with the desire of indoctrinating the seriousness of this problem. The U. S. Department of Agriculture has done its work so quietly and effectively in preventing this disease that many sanitarians have been lulled into a false sense of security so far as anthrax is concerned. Nevertheless, it should be recalled that the sum total of cases in our tannery workers is not small and that not so long ago there was a very acute problem created by the spread of the disease by shaving brushes. Also it should be remembered that while most of the cases are traceable to hides or wool, any animal product may act as the vehicles of transmission, *e. g.*, bone meal, and that while the pustular form is most common, Tulloch of Dundee has reported cases which acquired by inhalation and which closely resembled cerebrospinal fever.

Buzzards, dogs, wolves, and coyotes undoubtedly play a role in the spread of the infection and it is necessary to incinerate completely all animals dying of the disease or slaughtered as an eradication measure. Inoculation with the attenuated virus is a measure of prevention, but so long as we get animal products from countries having an indifferent veterinary service, the disinfection of raw materials des-

The Ceaseless Battle of Life

TRULY the way of the human race is beset with many dangerous pitfalls and man, the indomitable, must exercise constant vigilance lest he be destroyed. He walks unshod on Mother Earth and contracts hookworm; insects attack him through the air to introduce alien animals into his body; he drinks water and is injured or killed by enemy vegetables; his food is poisoned and he has botulism; he rides in chariots of fire and is killed; he navigates the jealous seas and is drowned; he mounts the wings of an eagle and is hurled to destruction; he associates with his fellow men and exchanges infections with them, while the lower animals transmit to him a variety of ills both when they are living and when they are dead.

A large portion of the work which sanitarians are doing is that of carrying on a constant warfare against these destructive agencies. The public health workers are so to speak, the regular army which engages these enemies in combat and trains the citizen so that he may carry on the battle for himself.

One of the most stubborn of them all is anthrax, which by its spore-bearing quality is able to resist many of the preventive measures which would be ordinarily applicable against the microbic infections. A disease of animals, its causative organism is present in many animal products which man cannot do without, hence those who come into contact with certain animals and their products run the risk of having this organism enter their bodies through the skin, the lungs or the intestinal tract. Since 1910, the French have maintained in the *Service de Prospection du Travail* an office for the study

of professional anthrax and for the collection of data relative to its occurrence in various parts of the world. The results of these studies for the years 1914-1919, inclusive, have been published (*Bul. de l'Insp. du Trav.*, *xviii*, 1920, p. 313 and *Bul. Int. d'Hyg. Pub.* *xiv*, 1437) and are valuable as showing how widespread anthrax is and the way in which it attacks those who work in or handle animal products. On account of the World War, considerable difficulty was encountered in the collection of these data, and but 157 cases were reported of which the country of origin was discovered in 91 instances as follows:

Spain (goat skins) 32; Africa, 20, including North Africa 5, Suez 1, Abyssinia 4, East Africa 1, Madagascar 2; Asia, 12, including, Arabia 4, India 4, Bagdad 2, China 2; South America 12, including, Argentine 8, Uruguay 2, Brazil 1; Macedonia 6; Russia 3; Greece 2; Mediterranean basin 3; and France 1.

Of the total of 157 cases, 56 occurred in leather dressing, 48 in wool-sorting and washing, 11 in wool picking, 11 in warehousing skins, 7 in the manufacture of horsehair, 4 in lightering, 3 in general stores of dry hides, 3 in tanneries, 2 in combing wool, 2 in carting, 2 in the commerce of skins and dry hides and 1 in each of the following; wool treatment, commerce of green hides, depots of dry hides, handling hides in docks and warehouses, commerce in hair and goats wool and one unknown.

The victims fall into the following professional categories: 35 vatmen (leather-dressers); 31 wool pickers; 15 handworkers in various establishments, including leather dressers 8, hide handlers 3, dock workman 1, shearers 1, wool picker 1, scraper 1;

tinued for industries working in animal products must be practised. As an additional safeguard, rubber

gloves, aprons, and boots should be provided for workmen handling such materials.

Tuberculosis in Childhood

TUBERCULOSIS in childhood is a baffling subject; to the physician because the opportunity for infection, though practically universal, is not possible to combat without early recognition. According to Charles Hendee Smith, in the March-April issue of the *Bulletin* of the New York Tuberculosis Association, the solution of the subject finds a further handicap in the fact that many physicians seemed inclined to discount the diagnostic value of the tuberculin test except in early infancy. "I have no patience," says Dr. Smith, "with the teaching that the test means nothing after one, or two, or six years. A positive reaction always means that a child has been infected, if we exclude factors of error."

Proceeding to give minute directions for the test and for interpreting its reactions, Dr. Smith goes on to say that such a test must be relied upon for the detection of the disease in children and childhood is the most important period in the history of the disease, because it is the true incipient stage. To save life diagnosis must be arrived at long before the lung is in-

involved, because pulmonary disease is usually acute and fatal in children.

The belief that all children are infected is based upon the early figures of Hamburger, Pirquet, and Escherich, from Vienna, notoriously the most tuberculous city in the world. The American statistics are quite different is evident from the chart shown herewith. The marked contrast between the cities of Europe and America should not, however, obscure the fact of tuberculosis in children as a problem of the first magnitude in America.

Phipps Institute Looks After the Health of the Negro

That the health of the negro population is of great importance to the whole community is the assertion of the Henry Phipps Institute of Philadelphia. As servants negroes go most intimately in the homes of the whites and are a constant source of possible infection there. For 1921 the census in Philadelphia showed a population of 1,823,779 whites and 134,229 negroes. The death rate of the former was 12.46 per 100,000 and of the latter, 15.55. The rate for tuberculosis alone shows that the negro is about four times as susceptible to the disease as the white. From this it is clear that the health of the community at large depends in a measure on the well-being of the negroes.

In the early years of the Institute, the negroes who came to the clinics, more or less by accident, could seldom be induced to persist in their attendance, and no considerable progress could be made with them as individuals. This situation was changed in 1914 by adopting the principle of operating through the medium of selected negro workers. Since its beginning this clinic has treated 2,116 negro cases of which 510 cases were cared for during the past nine months. The Whittier Center was induced to employ a colored nurse to work as a member of the staff of the Institute. It has continued to support a worker at the Institute Clinic, and at the present time it pays for the services of three graduate negro nurses.

Since 1915, the Philadelphia Health

Underwood and Underwood
This youngster is excited because he has overslept himself; but no harm is done, for he is on a roof top, taking the cure for tuberculosis. Rest is an important part of the cure, and fresh air essential.

Council and Tuberculosis Committee has augmented the staff of the Phipps Institute negro clinics by paying the salaries of two negro doctors and three nurses.

In order to increase the supply of negro nurses trained in tuberculosis work, six nurses from the Mercy Hospital have been given intensive training on the subject under the direction of the head worker at the Institute. The work of Dr. Minton, who is the chief of the negro clinic, deserves special mention. Having a capable negro doctor in charge has made an appreciable difference in increasing the numbers of patients attending the clinics.

The *Journal of Personnel Research* announces, to begin with the February-March issue a series of articles by Elton Mayo, late of the University of Queensland, on the psychiatric approach to the personnel problems of modern industry. Mr. Mayo is now connected with the Department of Industrial Research of the Wharton School of Finance and Commerce, University of Pennsylvania.

The Weekly Health Review of the Detroit City of Health gives the following criterion for the determination of a state of positive health in a subject under fifty: He should be able to run a hundred yards, or play two sets of tennis, or swim a quarter of a mile without undue fatigue. If over fifty, a walk of three miles, an afternoon of golf, or a few short swims should exhilarate the subject or render him just pleasantly tired.

The importance of tuberculosis in childhood as a public health problem is plainly indicated in this chart showing the incidence in cities of infection with tuberculosis, on the basis of percentage of positive skin reactions in the tuberculin test. The upper curves represent series reported from European cities and all show a higher percentage of positive reactions than in American cities. The New York series represent about fifteen hundred consecutive cases in the wards of Bellevue Hospital, children's medical division. Pirquet and intradermal reactions were done on all cases and nearly all the negative cases were retested with increased doses of tuberculin.

Recent Progress in Sewage Sludge Dewatering

By H. BURDETT CLEVELAND, CONSULTING SANITARY ENGINEER, NEW YORK CITY.

WITHIN the past few years definite realization has come to sanitary engineers that an efficient and economical handling of sewage sludge has been the outstanding, unsolved problem of sewage disposal.

To little consideration in the design of sewage treatment works has in general been given to the ways and means of sludge disposal. This has been due, primarily, in respect to American practice, to the absence of operating experience with large sized sewage disposal units and partly to lack of foresight. We have developed the art of removing the suspended solids from the sewage without developing much art in removing these solids from the sewage solids from the sewage treatment plants.

As a generalization, sludge drying on beds at sewage disposal plants serving large communities will not meet the necessities. Suitable areas are too restricted and sensitive noses are too numerous. The Back River, or main sewage treatment plant of the City of Baltimore, for example, is situated eight miles from the center of the city in what would appear to be so isolated a site as to present no real problem of property damage from nuisance. The plant is exceptionally well operated under expert supervision but the sludge must be dried on thirty acres of open sand beds, and the total awards of city funds by various injuries to aggrieved property owners in the vicinity, after only ten years operation of the plant, already represents considerable frozen capital.

It is for more cogent reasons than the economic salvaging of fertilizer values, however worth-while this may be, that the trend in sludge treatment is toward mechanical means.

The writer had the interesting experience recently, of testing the adaptability to the problem of sludge dewatering of one of the several mechanical methods that have been suggested or tried, and has become rather intimately acquainted with the difficulties involved.

Colloids, and in the case of activated sludge still more colloids, hygroscopic or fibre encased moisture, finely divided suspended matter and fats—there are the bunkers to be overcome to arrive at an inexpensive, inoffensive and efficient separation of solids from liquids in sewage sludge and insure the full economic and sani-

tary value of sewage treatment works.

The principal types of mechanical apparatus or processes thus far employed or experimented with in dewatering sludge are filter presses, centrifuges, vacuum filters, the sulfur dioxide process and the flotation process. Pretreatment or preliminary conditioning of the sludge, especially activated sludge, by the addition of lime, sulphate of alumina or acid or through the application of heat, is generally employed.

None of these processes have thus far been worked out on a practicable basis to what might be termed the point of reasonable economy of operation. Each process is applicable and is being employed or about to be employed at various existing and proposed sewage disposal plants for want of a cheaper, more effective method. It is clearly inconsistent that the cost of reducing the volume and of finally disposing of sewage sludge, which has little or no pathological significance, should bear such a high ratio as it does today to the total cost of sewage treatment when such sludge amounts in volume to only 1/1200 or at the most (with activated sludge) to only 1/80 of the total volume of sewage.

It will be of interest to review in a general way the more recent developments in sludge dewatering.

Filter presses for sewage sludge dewatering have been utilized in this country for over twenty-five years, sludge pressing plants having been operated at Worcester and at Providence. They are of two general types, the plate press and the platen press. No marked improvements have been made in the plate type in recent years although more satisfactory results are evidently being obtained with this type at Chicago through the conditioning of the sludge with sulphate of alumina instead of lime or sulphuric acid as heretofore. The platen press is a more recent development and has given promise of increased output. The operating cost of each of these types, however, is high, and their use in the sewage disposal field does not appear at present to be extending.

Centrifuges have been tested in this country at Milwaukee, Baltimore and Cleveland. At Cleveland, a small machine of the laundry whizzer type was used, with the inside of the perforated wall lined with duck. A fairly

clear effluent was obtained and the moisture content of the wet activated sludge was reduced from 98 or 99 per cent to a moisture content of the cake of 80 per cent. In the operation, a hard packed layer one-fourth inch thick, formed against the filter cloth, so reducing the output of the centrifuge as to make its use uneconomical. Similar experiences with this type of apparatus were recorded at Milwaukee.

At Milwaukee and at Baltimore, centrifuges of the non-perforated wall type have been tested. The first machine of the solid wall type with which experiments were carried out at Milwaukee, was fitted with a one-fourth inch inlet or sludge feed pipe which caused trouble from clogging. Moreover, the centrifuge was of such construction that it was necessary to stop the drum at the end of each run to remove the dewatered material, thus seriously interfering with the hourly output.

In October, 1920, tests were begun at Milwaukee with a solid drum wall centrifuge so constructed that the effluent could pass out of the top of the drum over a flat ring with its inner periphery five to six inches inside the outer wall of the drum. The centrifuge was so designed that the drum wall could be dropped automatically, without retarding the revolutions of the drum, for the purpose of discharging the dewatered material. The operation of the centrifuge was therefore continuous except for the half minute interval at the end of each run of ten to thirty minutes when it was necessary to discontinue the feeding of wet sludge, which was also done automatically, for the purpose of discharging the dried cake.

The diameter of the drum was thirty-six inches. The depth at the outside or discharging face of the cake pocket was ten inches and at the inner face or effluent overflow zone, eighteen inches. The capacity of the drum was twenty-six gallons. The sludge inlet or feed consisted of a fixed pipe extending through the central opening in the cover to a point near the bottom of the drum. The drum was operated at 1300 to 1720 r.p.m.

This centrifuge, as described above, reduced 98 to 99 per cent moisture activated sludge to a cake moisture of 80 to 83 per cent with a maximum efficiency of removal of suspended solids of 35 to 40 per cent at a sludge

inlet rate of 10 gallons per minute and with a maximum efficiency of removal of 25 to 30 per cent at a sludge inlet rate of thirty-five gallons per minute.

When treating semi-digested settling tank sludge at Baltimore, the centrifuge as described above reduced sludge of 92.5 per cent moisture to a cake of 71 per cent moisture with an average efficiency of removal of suspended solids of 70 per cent at a sludge inlet rate of six gallons per minute and with an efficiency of removal of 60 per cent at a sludge inlet rate of twelve gallons per minute.

At Baltimore recentrifuging of the effluent was suggested to accomplish a higher total percentage of removal.

At Milwaukee tests were made to determine a feasible schedule of operation, involving return of centrifuge effluent to the activating tanks, which would daily relieve the activating system of the necessary volume of suspended solids through the centrifuging of a sufficient excess volume of wet sludge over that normally produced by the process. However, the effect of the return to the activating tanks of the fine matter contained in the centrifuge effluent greatly reduced the percentage of removal accomplished by the centrifuge and also seriously interfered with the activating process.

The tests of this machine at the Milwaukee sewage testing station and at the Back River sewage treatment plant of the city of Baltimore were carried out by the writer during 1921-22 in cooperation with Mr. T. Chalkley Hatton, chief engineer of the Milwaukee Sewerage Commission, and Mr. M. J. Ruark, division engineer of sewers for Baltimore. It was felt that if the centrifuge should prove sufficiently effective and economical in operation to meet the requirements in this country as to quality of effluent and reduction of sludge moisture, it would have in its favor several features not typical of other mechanical methods, as follows:

(1) The operation of the centrifuge would involve no man-handling of sludge or of cake; (2) it did not appear from the tests that pretreatment of the sludge with lime, sulphate of alumina or acid was necessary or advantageous; (3) the labor and maintenance costs would be relatively low; and (4) the manner of operation would reduce to a minimum the production of nuisance conditions.

However, the performance of the centrifuge did not meet the requirements of the authorities at Milwaukee or at Baltimore and it was not adopted.

The vacuum filter is not new but its successful application to sewage sludge dewatering is new, having been accomplished within the past year. The type of vacuum filter referred to, known as the Oliver vacuum filter, was first tried out at Champaign, Ill., but the tests were discontinued.

Mr. Hatton described in the *Engineering News-Record* of February 1, 1923, the general features and operating efficiencies of this filter in connection with the tests at Milwaukee on which was based the decision for its adoption for sludge dewatering at the Milwaukee sewage disposal plant. The following brief description is based on Mr. Hatton's article and on limited observation of the tests at Milwaukee.

The filter used in the tests comprised a cylindrical drum or framework covered with wire cloth and duck. The drum was thirty-six inches in diameter and about twenty inches long with fifteen square feet of filtering surface. About three to four pounds of 80 per cent moisture cake per hour per square foot of filtering surface was produced from 98 to 99 per cent moisture activated sludge. The drum revolves, partially submerged, in a vat of heated and acidified sludge, the temperature of the sludge being raised to 150° up to 180°. The sludge is first formed into a mat on the outer surface of the filter drum by a light vacuum applied to the inner surface of the drum. The water in this mat is then removed by a heavier vacuum or suction.

This process produces a very fine effluent and is continuous. Also, the cost of clothing these filters is much less than that of replacing worn out bags in filter presses. The cloth is not subjected to abrasion and can be washed in place once every six to twelve hours. Good cake was readily produced in winter as well as in summer which was not always the case with filter presses at the Milwaukee testing station.

The equipment contracted for at Milwaukee consists of thirty drum filters each twelve feet in diameter by fourteen feet in length and having some five hundred square feet of filtering surface. There would seem to be some possibility that comparative results on a full sized unit may not be as satisfactory as on the small testing model although it may be found that proper control of the different vacuums over the full length of the filter can be maintained.

The inherent disability of this type of sludge dewatering apparatus lies in the fact that for efficient results the

sludge must be prepared beforehand by both heating and chemical treatment, thus placing an added burden of cost on the process. This process, therefore, in common with other similar methods, is not a true mechanical process.

If stress is laid on the very fine effluent obtained, the continuous operation feature, the effectiveness of the process under winter as well as under summer conditions and the certainty of operation coupled with low filter cloth and manual labor costs and justification can be shown for the comparatively high power and sludge conditioning costs, this process may be said to be a very satisfactory one.

The MacLachlan reduction process has been adopted for Houston, Indianapolis and Pasadena, and a partial use of the method is being made at Gastonia, N. C. This process consists of first conditioning or coagulating the sludge with sulphur dioxide and then draining and pressing it in a continuous filter device.

The dewatering machine, as recently improved, consists of a partially submerged screen drum covered with fine wire mesh on which the solids are intercepted, raised out of the wet sludge in sheet formation and drained. The suspended matter in the wet sludge is deposited on the screen drum through the effect of a head or difference of elevation between the wet sludge in the vat and the effluent within the drum, amounting to from six to twenty-four inches, depending on the volume of sludge flow being treated. An idler roll covered with felt picks the drained solids off the screen cylinder and a wooden idler cylinder subjects the sheet of drained sludge to a pressing operation before it is automatically removed by a scraper.

One machine, 40x84 inches, fitted with a felt roll 16 inches in diameter and 88 inches long, is said to produce 1,600 pounds hourly of 83 per cent moisture cake from 98 per cent moisture activated sludge at an operating cost of between five and six dollars per ton of dry solids produced. It is claimed that an efficiency of 92.5 per cent removal of suspended solids was attained during the recent tests at Houston.

This method, while apparently not burdened with as much power and sludge preheating cost as the vacuum filter, yet involves considerable cost for pretreatment of the sludge before the actual dewatering operation is accomplished.

The flotation process has been developed by experiments carried on at

Mount Vernon, New Britain, Urbana and elsewhere, and consists of the addition of sulphuric acid to the sludge, and the heating and handling of the sludge under such conditions as to cause the suspended solids to rise to the surface. The "floated" sludge, from 99 per cent moisture activated sludge, is said to have a moisture content ranging from 84 to 90 per cent and to be easily dried.

Considerable study is being given at various sewage disposal installations and experiment stations to the possibility of decreasing present costs of sludge dewatering by mechanical appliances.

The need of a satisfactory solution of this problem has been emphasized, recently, by the increase in favor of the activated sludge process of sewage disposal and the greater difficulty of dewatering activated sludge at low cost as compared to settling or Imhof tank sludge. This feature of the activated sludge process is, at present, in addition to the relatively high operation cost of the main process, a serious argument against the adoption of the system in many instances. It may not be the controlling factor as to choice of method of sewage disposal, especially where proper disposal site area is limited, a high quality of sewage effluent is desired, or a minimum in the way of expense is not demanded, but the difficulty of handling

such sludge, if not overcome, will continue to detract from the value of this system for certain locations.

And in connection with sewage treatment works employing either plain settling tanks or two story tanks for the sedimentation of suspended solids, it cannot be said that a satisfactory state in the art has been reached or will be reached, on either sanitary or economic grounds, until a clean, cheap mechanical process for disposing of sludge, not subject to seasonal or weather conditions, has been evolved.

Pennsylvania Plats Her Charitable Institutions

A tangible result of Pennsylvania studies of institutions which is intelligible to the whole public as well as useful to the department, is the map shown below which classifies and locates all state and semi-state institutions within the commonwealth. Under the present organization the Department of Public Welfare functions through four bureaus, each manned so as to collect and utilize information in its special field. The Bureau of Assistance has supervision over medical and surgical hospitals and homes for adults which receive state aid. The Bureau of Children concerns itself with the care of dependent, defective, and delinquent children. It also dis-

tributes the Mothers' Assistance Fund. The treatment and custody of the feeble-minded and insane are supervised by the Bureau of Mental Health. Penal and correctional institutions and the management of the industries carried on by prison labor are functions of the Bureau of Restoration.

A new policy has been instituted of apportioning state aid in strict accordance with the actual service rendered and the actual cost involved, the details of which are facilitated by placing the 170 institutions caring for state patients under a uniform accounting system. The plan will likely be extended to cover all phases of state aid. Economy by effort and a reduction of expense as well as a check upon quality by service rendered are thereby accomplished.

As a further provision against overlapping of effort and inordinate expense, the Department has created a Commonwealth Committee made up of representatives from the Department of Public Welfare, and a representative of the Advisory Board of the Department of Health, of the Educational Council, and the Industrial Board. This committee serves as a clearing house for the welfare plans of all the parties represented. It also serves as a connecting link between the Board and the county and local organizations.

STATE AND SEMI-STATE INSTITUTIONS OF PENNSYLVANIA

PREPARED FOR THE INFORMATION OF THE PUBLIC BY THE

PUBLIC CHARITIES ASSOCIATION OF PENNSYLVANIA

419 SOUTH FIFTEENTH STREET, PHILADELPHIA, PA.

The Pennsylvania Department of Public Welfare, created by Act of Assembly, in May, 1921, as a preliminary to its formulation of policies, undertook a comprehensive survey of all institutions. The information acquired was put in the form of a spot map for the information of the public.

Legislative Situation in Iowa

THAT the representative farmer takes an interest in public health and is willing to spend money where he can be shown that it is going to result in improved health conditions for his state and community, is demonstrated by the record of the Fortieth General Assembly of Iowa which closed April 17. This record explodes two mistaken notions which have some currency among people who do not understand the farmer and his problems—one notion being that he has been more interested in the pedigree and welfare of his hogs than of his children, and the other being that his sole purpose in coming to the state capitol is to save money by cutting out appropriations.

Sixty per cent of the Iowa house consists of farmers—real farmers, not merely ex-farmers or business and professional men from rural communities; and there is quite a strong farm bloc in the senate; so the Iowa legislature was a typical farming legislature. It did have in mind the purpose of saving money for the state and succeeded in accomplishing a number of economies. The purpose of reducing taxes is a most praiseworthy one at all times, and it is especially natural that a legislator in a rural state should be thoroughly imbued with such purposes, in view of the fact that business conditions since 1920 have been more oppressive with the farmer than with any other business group. An understanding of these facts makes the story of health legislation in the present Iowa Assembly still more remarkable.

By a vote of eighty-seven out of a possible total of 108, the House of Representatives cheerfully swallowed the so-called Rockefeller Bill which provided for an annual appropriation of \$450,000 for five years, to match a gift of two and a quarter million dollars from the General Educational Board and the Rockefeller Foundation for the enlargement of the medical department of the state university. By a similarly comfortable margin the senate committed itself to the promotion of scientific medicine. Affirmative votes on the Sheppard-Towner appropriation for maternity and infant hygiene work were about the same as the votes on the Rockefeller appropriation.

Among other health measures passed were the appropriation for Social Hygiene work, several measures

for the eradication of bovine tuberculosis, a play ground bill, and the bill for universal compulsory physical education and practical health instruction, and training in the schools. The legislature refused to amend the county hospital law and the vital statistics law in such a manner as to render them less effective, and a number of other measures inimical to the health of the state were quietly choked off in committee or reported for indefinite postponement.

The part played by the Iowa State Medical Society through its Field Activities Committee and Legislative Committee, working in conjunction, proved very gratifying to the profession.

The chairman of the legislative committee, Dr. W. W. Pearson of Des Moines, early in the session, arranged a dinner for the members of the public health committees, and the chairmen of several other committees of the house and senate. Over fifty members of the legislature were present at this dinner. The physicians who spoke stated the object of the get-together to be solely the desire to take opportunity to express the interest of the medical profession in public health. They offered whatever information and experience might be at their command which might be helpful to the law makers. A number of legislators responded informally.

The legislative work of the state medical society was done in a quiet way with a noticeable absence of letter writing, public meetings and the other usual methods of campaigning. The society confined its activities entirely to public health measures, and was represented in this contact with individual legislators upon public health matters by the executive secretary of the Iowa Tuberculosis Association—a logical arrangement, as the latter association, being the only voluntary statewide public health organization in Iowa has a continuing interest in public health legislation—represents the lay opinion of the various counties of the state in public health matters. There was close cooperation also with the Board of Control of State Institutions, the State Board of Health, the Commission on Animal Husbandry, the Department of Public Instruction; and the legislative interests of these departments inasmuch as they related to health were made a matter of friendly concern by the medical profession. The net result

seems to be that it is generally recognized that the state medical society carried out well the purposes to which it was committed last year in the creation of the Field Activities Committee, namely to activate the doctors of the state in the direction of impersonal and unselfish support of the up-building of community health through preventive measures.

In any survey of legislative results it is always impossible to apportion the responsibility for the success or failure of any particular bill, but it is generally conceded by those who are familiar with the situation that the three more conspicuous of these health measures, namely the Rockefeller, the Sheppard-Towner and the Physical Education Bills, would not have passed had the medical profession been either opposed or indifferent to them.

The experience of the maximum-hours-for-women bill illustrates this point. This bill failed because it was made to appear that there was considerable division of sentiment among women's groups.

Several members of the legislature reported that various physicians had come to them before the opening of the session and had asked them to oppose the Sheppard-Towner appropriation. Near the beginning of the session the Field Activities Committee and the councillors of the state society made a thorough investigation of the Sheppard-Towner work to date, asking the men employed in this work to appear and answer all questions fully. They decided that the opposition of physicians in this state and the opposition of a portion of the medical fraternity throughout the country arose from lack of information on its purposes and functions. They sent out a letter to every county medical society in the state making it plain that the maternity and infant hygiene work was not a step toward state medicine, that it did not provide for any treatment or medical or nursing service, that it was educational and diagnostic only, and that it would serve both to increase the business of the local physician and improve the health of the local community.

Results already noticed are the increase of a friendly attitude on the part of large groups of lay people interested in public health toward the medical profession, an increasingly close cooperation between these elements, and a conviction of the sincerity of the organized physicians of the state in their professions of loyalty to the public health movement.

Public Health Aspects of Drug Addiction

THE widespread prevalence of drug addiction constitutes a situation which may well provoke serious thought on the part of the profession of preventive medicine. It is no exaggeration to state that we are face to face with a condition which, if uncontrolled, may tend to undermine the very foundations of civilization itself. So serious is this threat that half-way measures will not do; the circumstances are such as to call for drastic and thoroughgoing measures. These are not the alarmist beliefs of fanatical reformers, but the sober judgments of capable physicians, wise jurists, and well balanced men and women who know from personal experience and observation the way in which the great army of drug addicts is being recruited daily and the misery and degradation which is thus produced.

It is a horrid thought that modern chemistry and therapeutics should have let loose upon humanity agents which have been diverted from their original purpose of relieving human suffering to that of debasing and destroying mankind. Prohibition, the stress of modern life, the *ignis fatuus* of a desire for new sensations, mental degeneration, and the criminal carelessness of the

medical profession in prescribing habit-forming drugs have all been blamed for this destructive blight which civilization has imposed upon itself, but these are only mildly contributory. The real cause is much simpler and far more sordid. The production and sale of narcotics pay enormous returns upon the original investment. The basic source is greedy avarice.

Great international organizations have been formed for the marketing of narcotics. They ruthlessly violate any law of God or man to carry on their debasing trade. They fearlessly corrupt customs officers, the police and the very courts themselves in order that their contraband may reach and destroy the consumer. Certain physicians have even so far prostituted their professional standards as to become panderers to habitués, and men of responsibility in the community have so yielded to the pressure of the dollar that they have protected drug peddlers from punishment by the law. From the fields of Turkey, Persia and India where the opium poppy is grown and the forests of South America and Java where *Erythroxylon coca* is raised, through the chemical works of the United States, England, France and Germany, out to the ports of the world, to centers for the distribution of the drugs, to the scoundrelly vendors and their unfortunate

victims, there runs a sinister line of bribery, smuggling, bestiality, deception, and murder, energized by lustful avarice and greed.

Up to date these dark forces have been largely combated by a small group of practising physicians, the legal machinery of the Federal government and of the various states and municipalities, and a few public spirited volunteers. In a few instances these leaders have been assisted by public health workers. They have not always displayed the greatest wisdom in their well meant efforts, but they have honestly and wholeheartedly pitted themselves against this octopus which is stretching out its tentacles into every walk of life and every stratum of society. This group is dealing with end results and consequently is failing to affect materially the elemental cause. There is a very genuine public health problem here and it is our duty to attack courageously this mental disease which menaces industry and public safety, which has invaded our hospitals, asylums, and penitentiaries and has even made serious inroads upon the army and navy. Once largely confined to the criminal classes, it is now not uncommon to find the vice in the higher walks of life and, worst of all, it is claiming as its victims many youths and adolescents. The disease must be regarded as a highly communicable infection since one of its outstanding symptoms is the desire to induce others to acquire the habit, and like other dangerous contagions, it must be fearlessly attacked and eradicated.

This is not to be done easily. There is no universal panacea for the cure or the prevention of the drug habit. It is a secret mental vice which does not show itself early in the facies or comportment of its followers. It is easily contracted, and if followed for a single week may fasten itself firmly upon the unwary. It is difficult to cure, relapses and reinfections being frequent. The dope-fiend is a potential criminal from the beginning and brooks no restriction which will prevent him from his eventual self-destruction. The forces which are producing and marketing narcotics are strongly entrenched and they will not draw back from any crime in order that they may continue their profitable occupation.

We may, and we must, arrest, prosecute, convict and punish; we may, and it is our duty, to treat the miserable habitués; we may propagandize in the hope of securing prevention through education; we may, and we should do all these things wholeheartedly, but we may do them until the end of time and never make any real progress. Just so long as there is not an absolute control of the production and sale of drugs there will be weak men to crave them and scoundrels to

sell them. The place to cut off a snake's tail is just behind the ears. The place to attack this international menace is at the source, to control the raw products at the plantation, to regulate chemical works and their output to the extent that every grain of a habit-forming drug is accounted for up to and including the point where it is administered by a physician to meet an undoubted therapeutic necessity.

The figures in regard to the production of habit-forming drugs are appalling. In 1920 there were imported into the United States 127,248 pounds of opium, approximately 6 2-3 grains per capita, enough to kill every man, woman and child between Canada and the Rio Grande. In the same year Great Britain exported over nine tons of British-made morphia to other countries is significant that over 45 per cent of the English exportations of 1921 went to France, where the international drug ring is supposed to have its headquarters. Importations of opium into the United States are reported to be falling off but cocaine is coming in in greater quantities and in far greater amounts than are necessary for the therapeutic prevention and relief of pain. It should be borne in mind that in addition to the quantities which are declared at ports of entry, an enormous amount is being smuggled into the country and delivered to consumers with devilish ingenuity. Customs seizures of narcotics at the Port of San Francisco alone are reported to exceed \$162,000 in 1922. For every dollar's worth thus seized it is probable that at least ten dollars worth is smuggled in.

Under the system developed by modern banking it is possible to transport and deliver money to any part of the world with scarcely the chance of a single loss. The same sort of system should prevail with regard to the habit-forming drugs. It is possible to put it into force if the nations of the world will get together and rigorously carry out a united policy. The Hague Committee tried to bring about such an arrangement and failed. The League of Nations now has a board sitting to formulate plans with the same object in view. The United States has sent observers to the meeting apparently to lend the moral influence of an onlooker sitting on the fence. Whatever may be our views regarding "entangling alliances" this is no time to be hanging back timidly. The international traffic in dangerous drugs is not a political question, it is a great health issue. It is an affair of the greatest possible moment. It is a responsibility which, if dodged by us or if not met in the open by our people, is going to do us an infinitude of damage. We cannot sit by as critics. We must get into the fight instead of tell-

ing the other nations what they should do and how they should do it. It is just as much our fight, just as much of our interest as would be a devastating plague epidemic in Europe, Asia or Africa. The civilized world must combine against this menace and we must not be too proud to fight an enemy which threatens the integrity of civilization.

Prevention and Cure Remain Essentially Indistinguishable

THE classical distinction between preventive and curative medicine is a simple and attractive one; but one wonders sometimes how fundamentally significant it really is.

If a water supply is purified so that the opportunity for transmitting typhoid fever by this means is eliminated, we are indeed dealing with prevention in the strictest sense. The isolation of a case of scarlet fever may, in similar fashion, protect other potential victims from the possibility of exposure. On the other hand, the work of the tuberculosis clinic, which we are apt to think of as preventive medicine, involves in its essence the detection of incipient disease, and the checking of its future development, just as truly as do the early diagnosis and the surgical treatment of the cancer. The prenatal clinic and the infant welfare station deal primarily with the well, yet one of their most important functions is again to detect incipient disease, and secure treatment that will check its further progress. The whole campaign for dietary hygiene in the schools is based largely upon the detection of the undernourished child, by systematic weighing and measuring. It is too, in a sense, the treatment of incipient disease, although the methods of treatment are hygienic rather than pharmacological.

As a matter of fact the object of most "curative" medicine is to prevent the further progress of a disease process. It is curative as applied to what has passed, but it is preventive in relation to what would have otherwise resulted in the future.

If we regard the problem philosophically the same interrelationship of prevention and cure stretches back to include every procedure of personal hygiene which is adapted to the particular idiosyncrasy of the individual. Throughout a large sector of the Public Health Campaign, prevention and cure are essentially indistinguishable. In the future the hygienist will more and more look backward to consider the personal characteristics of the individual as they have effected the present state of his health, and the physician will look forward to the development of health habits which will prevent physical disability in the future.

The Newer Developments in Nursing Education

THE report of the Rockefeller Committee on Nursing Education¹ is already beginning to bear fruit. During the month of May two announcements of the first importance were made, one in regard to a gift from Mrs. Chester Bolton of a half million dollars for a central school of nursing at Western Reserve University in Cleveland, and the other dealing with the establishment of a university school of nursing at Yale. We are not familiar as yet with the details of the Cleveland plan but the principles on which the Yale school is to be established are discussed in another column and it is clear that this step is truly of epoch-making significance in nursing education.

The new school at New Haven is to offer a course probably somewhat shorter than that now in general vogue and a course to be dominated throughout by the modern spirit of community service, which demands that both the nurse and the physician should be public health workers in the highest sense of the term. More important than any details, however, is the fact that the school at Yale will be organized as an independent school of the university under the direction of Dean Annie W. Goodrich and that it will in every way be independent of any hampering considerations, free to work out in experimental fashion the length of course and the type of course which will produce the high type of nursing service for which there is such crying need. We have other university schools of nursing which are rendering splendid service, but so far as we are aware there is no other which stands as an independent university unit with neither hospital nor medical school nor graduate school control. The Yale School faces the future untrammelled in every way, and with a leader in the person of Miss Goodrich whose experience and courage and initiative fit her most admirably for a new and constructive contribution to the cause of education.

The Work Accidents of Children— Their Prevention in New York

LARGELY with a view to discouraging the illegal employment of minors in occupations where the accident hazard is high, legislation has been introduced in New York state to provide for double accident compensation and double death benefits, in the case of a minor employed in violation of the labor law.

This legislation is based on a recent report

1. Printed in full in our columns, July, 1922.

by the Bureau of Women in Industry. The Bureau analyzed the compensated accidents—accidents which caused a disability of two weeks or longer—of children under eighteen years of age, over the period of a year.

Forty-four children whose injuries were serious enough to be of two weeks or longer duration, were illegally employed. For example, a boy twelve years of age lost two fingers in feeding meat into an electric chopper; a girl thirteen years old lost two fingers while employed at candy cutting; a boy only eleven years old employed to run an electric ice cream freezer mashed his hand while working. A boy of fifteen was injured in the operation of an elevator, while the law fixes eighteen as the minimum age for elevator operators. There were also fifteen accidents in which the child was injured cleaning machinery while in motion—another violation of the law.

The essential features of the double compensation plan are that children who are injured while employed without working permits or in prohibited occupations, shall receive in compensation two times the amount to which they would be entitled if they had been legally employed. It has been the experience elsewhere that a real deterrent to the illegal employment of children lies in the fact that when children so employed are hurt or killed in the course of their work, the employers involved are obliged to pay more in compensation than if the industrial workers were employed legally.

Another outstanding feature of the investigation is the large number of accidents occurring on metal cutting or stamping machines. This industry and this type of machine may be blamed for the largest number of compensable accidents. One factory with a normal working force of six had fifty accidents in one year—all serious and all occurring to comparatively young boys. Children under sixteen years are now prohibited from operating or working on metal cutting or stamping machines, and the report recommends that the age be extended to eighteen.

The carelessness, irresponsibility, and natural curiosity of children, coupled with their lack of coordination at the adolescent age, makes them peculiarly susceptible to accidents. Children by the very nature of their youth are less able to protect themselves than those who are more mature and, therefore, more steady. The spirit of play is much stronger in children than the spirit of work; they will play now and then in factories, regardless of the danger from machinery.

Furthermore, even when an accident is not fatal, total or partial disability to a young person involves a greater social loss than does the same

accident to an older person. The loss of a hand to a seventeen-year-old boy affects his entire working life and determines in large measure his contribution to the community. For this reason alone the protection of working boys and girls from industrial accidents is highly important.

The tendency throughout the country is gradually to raise the age limit at which children may go to work. It is hoped that the time may come soon when all children may have at least fifteen years for play and education before industry claims them.

Standard Engineering Safety Codes

THE work of the American Engineering Standards Committee¹ is one of the outgrowths of the war which is proving of substantial and increasing value. Its first meeting under its present organization was held October 19, 1918. It is made up of representatives from the leading professional engineering societies of the country and its purpose is "to serve as a national clearing house for engineering and industrial standardization, to act as the official channel of cooperation in international standardization, and to provide the information service on engineering and industrial standardization matters."

The particular aspect of the committee's work in which we are most interested is the formulation of safety codes, which appears to be one of the most important functions of the Engineering Standards Committee, since its year book for 1923 indicates that nearly forty codes have been issued or are now in process of study. The National Safety Council, the American Society of Safety Engineers, the United States Department of Labor, the International Association of Industrial Accident Boards and Commissions, and various casualty organizations have actively cooperated with the committee and of the thirty-five standards thus far finally approved by the A. E. S. C. the following ten deal with problems in which the readers of *THE NATION'S HEALTH* are more or less directly interested: Specifications for fire tests of materials and construction; code of lighting factories, mills, and other work places; safety code for the use, care, and protection of abrasive wheels; safety code for the protection of industrial workers in foundries; safety code for power presses and foot and hand presses; regulations for electric wiring and apparatus in relation to fire hazards; electrical safety code; automobile headlighting specifications; and specifications for the testing and use of permissible ex-

1. Address 29 West 39th St., New York City.

plosives; and safety code for the protection of the heads and eyes of industrial workers.

The work of the Engineering Standards Committee has so far been conducted with caution and with excellent judgment and it promises to render a far-reaching service in the field of industrial hygiene.

The Coming International Health Education Conference

KNOWLEDGE of the color, the mystery, the splendor of the world is unrolled at the feet of the children in our schools just as beautiful rugs are spread out before shoppers in an Oriental bazaar. We have learned that this knowledge is not enough. Into it must be woven health, the talisman that transforms education into a magic carpet of usefulness and power.

The National Education Association has given child health an important place in the World Conference on Education to be held in Oakland—San Francisco, from June 28 to July 6. In connection with this conference, an International Health Education Conference has been arranged to discuss the aims and ideals, the subject matter, and the methods of health education in relation to all school-age children; and, at the request of the Foreign Relations Committee of the N. E. A., the details of this conference are being planned by the American Child Health Association.

In order to get together leaders in the various fields of sound and vital health education, invitations have been issued to biologists, doctors, nurses, nutrition specialists, psychologists, physical educators, teachers, health workers, and educational administrators in seventy-two countries. The program has been prepared through the cooperation of the American Child Health Association, the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, the American School Hygiene Association, and the Departments of Child Hygiene and Physical Education of the N. E. A.

The subjects to be discussed in the sessions of the Conference are:

Health Education in the World Today.

The Place of the Nurse in Health Education.

Contribution of Physicians and Dentists to a Health Education Program.

Contributions from the Field of Nutrition to a Health Education Program.

Physical Education in Relation to the Health Education Program.

The Essentials to be Considered in Developing a Health Education Program.

Preparation of Teachers and Supervisors to Carry on Health Education Work.

The Contribution of Non-School Agencies to the Program of Health Education.

Back of it all stand the teachers of the world unrolling their beautiful rugs of knowledge for children to buy with the hours they spend in the classrooms. These skillful, earnest teachers must be given an impelling desire to weave health-magic into the education they pass on. Training them to be worthy members of the Guild of the Magic Carpet, will be an especial concern of the International Health Education Conference.

The Field for Fan Ventilation

THE tendency to overemphasize new developments in science and to apply them where they are not properly applicable is a constant source of error and inefficiency. There is a real danger that a mistake of this kind may be made in interpreting recent advances in the practice of ventilating occupied rooms by gravity systems rather than by forced fan ventilation.

The recent report of the New York State Commission on Ventilation¹ with its conclusion that "window ventilation with ample direct radiation, window deflectors and adequate gravity exhaust, seems the most generally promising method for the ventilation of the class room where local conditions permit its use," is certain to exercise a far reaching influence on the art of ventilating school houses. On the other hand, the commission is careful to point out that "there will be many schools in which this method can not be applied. Where noise, and dirt, and odors from the street make it inconvenient to have windows open the use of the plenum system would, for instance, be clearly indicated; and where class rooms are markedly overcrowded, window ventilation would be likely to prove inadequate." Furthermore, the commission emphasizes most strongly the fact that its conclusions apply only to the school room, and that other types of buildings will require different treatment. For crowded auditoriums and factories the commission specifically states that "fan ventilation is likely to supply the only adequate solution of the problem." In particular it must be realized that the removal of dust and fumes, a procedure whose importance is more and more clearly recognized by experts in industrial hygiene, must in general be accomplished by special exhaust ventilation. The ventilating fan has its very definite place of usefulness and the improvement and simplification of school room ventilation should not obscure this fact.

HEALTH IN INDUSTRY

*Problems Concerning Factory Sanitation,
Industrial Medicine, and the Health and
Efficiency of the Industrial Worker*

Notes on Industrial Medicine in Great Britain

**Lead Poisoning, Anthrax, Cancer
Are the Conditions Discussed**

By T. M. LEGGE, M. D., MEDICAL INSPECTOR OF FACTORIES, LONDON, ENGLAND.

I PROPOSE to state briefly some of the problems in industrial medicine which have presented themselves recently in Great Britain.

Lead poisoning dominates other forms of industrial poisoning, and a quite new industry—if it can be so called—that of shipbreaking, has, during the last two years, supplied as many as twenty-four cases. Curiously, just as we had learned by experience how to deal with lead dust, this new industry presents the more difficult problem of lead fume which, although in its ultimate form particulate, is in so fine a state of division that it will pass through many layers of cotton wool. The industry follows on the war, and in the scrapping of battle-ships use is made of an oxy-acetylene flame to cut through the armor plating. In addition to the paint, at the back of the plates is a layer of red lead at least an eighth of an inch in thickness. The flame, at a temperature of between 1,450 and 1,600 degrees C., causes volatilization of the lead from these surfaces. Aspiration of the fume during the process showed the amount of lead present in ten cubic meters of air to be forty-nine milligrams, and as I regard anything in excess of five milligrams dangerous, the poisoning is not difficult to understand. A workman, sometimes even after so short an exposure as three weeks, has been affected. The channel of absorption must obviously be entirely by way of the respiratory, and not the digestive, tract, and so in

New industries account for new diseases. Inspection everywhere is demanded to safeguard the workers, and every new process must be scrutinized for its inherent hazards.

Each industry constitutes a separate unit for investigation as to morbidity, general and specific, within its ranks, and hygienic codes are thus developed for its control.

The avenues of trade create international relationships in industrial medicine. Certainly the results of all research in industry should be subject to international exchange.

a measure sets at rest the dispute as to whether lead is absorbed into the system through the lungs or through the intestinal tract.

New Dangers from Lead

The operation of shipbreaking is being carried on in at least twenty-five sea ports, in some intermittently, in others as the chief business and one likely to continue for years. Periodic medical examination is the only remedial measure of value, but this is not popular with the workmen who, on showing symptoms of absorption, may be transferred from more highly paid dangerous posts to others free from risk but less remunerative. Respira-

tors of various types, with filtering material, have been tried without success. Fortunately, much of the work is done in the open air.

This, however, is not the whole story. My colleague, Dr. Bridge, found during his examination of the men employed in oxy-acetylene cutting that many of them complained of attacks of malaise and shivering coming on some hours after leaving off work, and likened to malaria by those who had served in the east during the war and suffered from this disease. These attacks showed all the characteristics of "brass founder's ague" and it was elicited that they occurred after the men had been working on craft the plates of which had been galvanized. Around the path of the flame, a white deposit of zinc oxid appeared, and in estimating the amount of zinc present in the fume given off from galvanized deck plates sixty-four milligrams in ten cubic meters of air were found. Indeed, the discomfort from this zinc fume, although not so serious in ultimate result as that from lead, is the greatest cause of complaint.

The Joint Industrial Council of the Printing and Allied Trades, at which employers and employed meet to discuss matters affecting conditions of work as well as wages, has taken interest in giving information to its members on such matters as general working rules, spread of consumption, and lead poisoning. I was asked to draw up a leaflet on the last named, and worded it as follows:

LEAD POISONING AMONG PRINTERS— HOW CAUSED AND HOW BEST PREVENTED

Lead poisoning is a risk in the printing industry, but not a great one when the number of persons employed is borne in mind. All reported cases are followed up to find out the cause which can quite definitely be said to be due to the inhalation or breathing in of either dust or fume containing lead. Thus in the last twelve years there have been 230 cases—98 compositors, 55 stereotypers, 20 linotypers, 14 monotypers, 2 electrotypers and 41 other persons mainly employed in the foundry. Of this total 160 occurred in ordinary letterpress printing, and 70 in newspaper printing works. But the most remarkable thing is that no fewer than 185 factories were involved, which means that the conditions exposing to risk of lead poisoning must be pretty much the same in nearly every printing works in the country.

Every reported case, it should be remembered, means others who are suffering from the effects of lead in a less degree.

Dust of metallic lead or the oxid of lead—the most dangerous form—given off in drossing or brushing the plunger of the lino pot, if absorbed even in small quantities, has a tendency to remain in the system. Unless, therefore, constant care and cleanliness are observed lead will go on accumulating so that in time the health may become damaged without the occurrence of any definite attack recognized as lead poisoning. The average age of printers when attacked is thirty-eight and the duration of employment fifteen years.

Handling of type metal and fresh type is harmless. The compositor gets his lead poisoning from the dust in the type cases; the stereotyper and foundry worker from drossing the molten metal, careless dumping of the dross on the floor and subsequent sweeping up and bagging operations; and the linotype from brushing the plunger, and possibly from the fine dust of metallic lead which drops down from the matrices as these are removed after contact with the slug. Finally, the debris on the floors is a cause.

As lead never enters the system directly through the skin, it can be prevented in printing works by avoiding the raising of dust.

It is to the interest of everyone to see that ventilating arrangements are as good as they can be for carrying away, at the point they are produced, dust and fume in the foundry and stereo department, and that proper trays are in place under lino and monotype machines and circular saws.

See that the dross is kept in a receptacle under the same hood as the melting pot, or, if that is impracticable, at any rate in a receptacle with a lid. *Never dump it on the floor.*

Although the temperature of the lino and mono pots is not high enough to give off lead fume, ventilating hoods and ducts, in connection with a fan, serve a threefold purpose: (1) in taking away the gas and oil fumes; (2) in keeping down the temperature

of the room and so making working conditions comfortable; and (3) in tending to draw away lead dust in the air.

Nowadays with either a dust extractor for compositors' cases in large works or a vacuum cleaner in small and with dust-proof plunger cleaners available, there is no excuse for blowing the type cases out with a bellows, or for wire-brushing the plunger in the open shop.

A worker can do much to keep fit and so make his system more resistant to lead absorption than it otherwise would be. He should pay scrupulous attention to cleanliness of the hands and teeth. Too much stress cannot be laid on the part played by bad teeth in lowering the health. The habits of the workers, intemperance, and disregard of the simple rules of health, as no one will need to be told, influence liability to lead poisoning.

Medical advice should at once be sought if signs of lead poisoning present themselves. Wrist drop will always incapacitate a man for months, and may prove permanent unless electrical treatment is obtained in time.

The interminable dispute as to the relative merits of lead and leadless paints was believed to have been advanced a stage at the International Labor Conference held in Geneva in 1920, when a draft convention was voted prohibiting (with certain exceptions) the use of white lead and sulphate of lead in the internal painting of buildings, while allowing their use for external painting, subject to certain regulations. Two committees, appointed in Great Britain in 1911, to investigate lead poisoning in house painting and coach painting, both recommended the prohibition of white lead altogether, with the exception of a small percentage.

Danger in Lead Paints

A further committee which was appointed in 1921 to re-examine, more particularly in the light of the further information which has become available since the inquiries of the committees appointed in 1911, the question of the danger from the use of lead paints, and the comparative efficiency and cost of paints containing lead and leadless paints respectively, has just reported in favor of acceptance of the fundamental principle agreed to at Geneva.

I believe that all lead poisoning in painting comes from the dust given off in dry sand papering, and that if there were no dust there would be no lead poisoning. Recently waterproof sandpaper has come on the market, and undoubtedly marks an advance in this direction. Indeed, it is considered by some, that if it were possible to enforce its use, even in the painting of private houses—into which no

inspector will ever be allowed to enter as for him to do so would be an infringement of the principle that "an Englishman's house is his castle"—it would make prohibition unnecessary. Personally, I think that some measure of prohibition on the lines of the Geneva convention meets the necessities of the case and will be able in time to remove the bugbear of lead poisoning from the painters' trade.

The committee's report should go a long way towards removing the bogey of turpentine poisoning. On this point—and it was very fully gone into in the evidence—the committee says—

Having carefully examined the available evidence we conclude that there is not sufficient ground to warrant us in accepting the view that turpentine poisoning is the cause of the leading symptoms commonly attributed to either acute or chronic lead poisoning, nor in attributing to the inhalation of the fumes of turpentine and other thinners the occurrence of chronic Bright's disease.

Another point of importance which the committee advocates is the appointment of a technical committee for the investigation of problems connected with paint technology which demand solution in the general interests, and on this committee they recommend should be represented: Paint-using departments of the Government; painters—employers and operatives; manufacturers of pigments; architects; and chemists.

The international character of anthrax among animals—which is transmitted to man through animal products such as wool, hair, skins and hides—has been brought up by discussion of the subject of disinfection and other measures for its prevention through the intervention of the International Labor Office in Geneva. Although work people are very stoical in their attitude to industrial diseases, anthrax is the one which causes alarm among them more readily than any other, no doubt because of the suddenness of its onset and the rapidity with which it progresses. Further, it is no respecter of persons, and is just as likely to attack a strong, healthy man as one who is weak. The danger also is a continuous one to the worker in infected materials. The public, however, have an erroneous idea of the fatality of the disease—it is often thought to be invariably fatal. While this is true of the rare form of internal anthrax (true wool-sorter's disease) it is far from the case in regard to external anthrax (malignant pustule) in which the fatality varies from 10 to 25 per cent. Early diagnosis and prompt treat-

ment have undoubtedly lessened the number of fatal cases. In general, the best treatment for a case of anthrax is physiological rest of the part affected, combined with intravenous injection of anti-anthrax serum—60-80 c.c. on the first day and 60 c.c. on the day following, if there has been no reaction (shown by a rise of temperature) and the general condition has not improved. Excision is unnecessary; subcutaneous injection into the abdominal wall of 30 c.c. has been successful in many cases, repeated, if necessary, on successive days. Difficulty is always met with in estimating the efficacy of different methods of treatment of a malady such as anthrax, which is capable of undergoing spontaneous cure. The examination of results of various forms of treatment in eight hundred cases of *cutaneous anthrax*—excluding the erysipelatos form—in Great Britain, support this conclusion:—

Treatment		Mortality	
	Cases	Deaths	per cent
Serum, only	200	8	4.0
Excision only	397	44	11.1
Excision and serum	174	25	14.4
No special treatment	29	14	48.3
Total	800	91	11.4

In Great Britain cases have been most numerous from the woolen industry, and the British government has erected an experimental wool disinfecting station at Liverpool to carry out the "Duckering" process (so called from the name of the inspector of factories who worked out the principle). This carries out disinfection in two stages, first by mechanical washing of the wool in a dilute alkaline solution at 102 degrees F. in order to remove the albuminous matter surrounding the anthrax spores, and then, having done that, to subject it to disinfection in two successive baths of a 2.3 per cent solution of formaldehyd at 106 degrees F. The entire process occupies 1½ hours. During the six months between April 1 and September 30, 1922, over seven million pounds of wool and hair were disinfected, of which no less than 123,000 pounds were sent voluntarily by employers fearful of the risk of anthrax in their works. At present, unfortunately, the station is not large enough to cope with all the wool and hair requiring disinfection.

It was to secure extension of this process in the countries of export that the matter was referred to the International Labor Conference.

The Advisory Committee on An-

thrax, convened by this conference, met in London in December last, and on the subject of infection from wool and hair the conclusions arrived at were: (1) That hair used in the brush-making and upholstering industries shall be disinfected before the materials are handled industrially; (2) that wool and hair to be used in the textile industry shall be disinfected before the materials are handled industrially, except in the following cases:— (a) if the country of origin is included in the schedule of countries where the danger is slight, (b) if the material to be imported has already been disinfected by a process recognized as effective, (c) if wools and long hair have to be sorted before washing, unless these products are not included in the list of harmless products, and (d) in such other cases as may be determined by the committee. The experts who had come to give evidence agreed that the proportion of wool imported into England which does not require sorting before washing is extremely small, and that it is almost always this kind of goods which gives rise to the danger of anthrax among the workers; that if it were possible to sort the wools after washing, it would be bad from the commercial point of view.

The production of cancer by specific forms of irritation was a subject somewhat fully discussed at the annual meeting of the British Medical Association in July last, and served to show how important are the figures now available from the notification by medical practitioners of epitheliomatous ulceration from pitch, tar, and paraffin in their bearing on the experimental work now being carried on in this and other countries. In this connection, Dr. A. Leitch recounted the first instance of successful experimental production of cancer by arsenic and by crude shale oils containing paraffins. The unexpected occurrence of this condition from lubricating oil was brought out by Dr. Southam and Dr. Wilson, of the Royal Infirmary, Manchester, who showed that of 141 cases of scrotal epithelioma treated in that institution between the years 1902-1922 the occupation in sixty-nine was mule spinning.

Since the requirement was placed on medical practitioners to notify epitheliomatous ulceration in 1920, one hundred persons have been so reported—one of them no less than three times and seven of them twice. Eighty-four were over 40 years of age, and the duration of employment in eighty of them was over ten years.

Mortality of Brass Workers Analyzed by Dr. Hoffman

Interesting information recently received from Frederick L. Hoffman deals with the mortality of brass workers. The secretary of the Brass Workers' Union kindly furnished Dr. Hoffman with the details of 116 deaths in the experience of that organization and the latter has classified these by causes, duration of membership in the union, length of service, and length of illness.

The analysis shows that the proportionate mortality from tuberculosis was 15.5 per cent for all ages, ranging as high as 44.4 per cent at ages 35-39. The proportionate mortality from respiratory diseases was 17.2 per cent for all ages, having been as high as 40 per cent at ages 25-29. In both these instances, however, the numbers are, unfortunately, too small for a safe generalization.

A comparison of the number of deaths with reference to length of trade life is of unusual interest. This shows that of the total 116 deaths 8 were in the group having a trade life of 1-4 years; 23 in the group having a trade life of 5-14 years; and 85 in the group having a trade life of over 15 years. Of the total 85 deaths in the last group over 75 per cent occurred between the ages of 45 and 64. "It will be observed that the major portion of the deaths occurred among members who had been fifteen years in the trade, or longer. This in itself would seem to suggest that the health-injurious consequences of employment in brass working were not as serious as has often been assumed. There have, unquestionably, been improvements during recent years, as the result of far-reaching changes in methods of ventilation and dust control."

Seventy-nine of the deaths were the result of illnesses lasting less than four months while 37 resulted from illnesses of a greater duration—"it is obvious that much of the mortality was the result of acute diseases of comparatively short duration. It would require a much longer exposure to justify definite conclusions, with a due regard to the nature of the illness dealt with."

"While the experience under consideration is not sufficient for very definite conclusions," says Dr. Hoffman, "it is certainly suggestive of a direction in which trade union data could be utilized to much better advantage than has heretofore been the case, in illustrating the complex inter-relation of occupation to health."

Industrial Rehabilitation in Oregon

A COMPLETE program, an all-embracing workmen's compensation system, should include the following: (1) A safety program that will reduce the number of industrial accidents to a minimum. (2) Compensation benefits for those who are injured, including complete medical, surgical and hospital care; payments for time loss, for permanent partial disabilities, for permanent total disabilities, and for widows and orphans and dependents in event of fatal injuries. (3) Physical rehabilitation. (4) Vocational rehabilitation. According to recent advices from Will T. Kirk, Commissioner of the State Industrial Accident Commission, Oregon has such a program, which is being carried out under the direction of the Commission in a practical way.

This state was the first to undertake the physical rehabilitation of its injured workers as a regular feature of its workmen's compensation system, and it also led the states in its vocational rehabilitation work because from the beginning the Commission was given ample funds and authority to take hold of the job in a business-like manner.

In launching its physical rehabilitation program early in 1920, the Commission undertook to put a literal interpretation upon the provision of the Oregon Workmen's Compensation law which says: "One purpose of this act is to restore the injured person as soon as possible and as nearly as possible to a condition of self-support and maintenance as an able-bodied workman, and final settlement shall not be made in any case until the Commission is satisfied that such restoration

is probably as complete as it can be made."

The Commission established a physiotherapy or physical reconstruction clinic in Portland and in Salem.

The physiotherapy department is one of the most completely equipped in the United States, and these men are given treatments to lessen time loss, and to restore function and thereby reduce the amount of permanent partial disability. It is equipped to make all sorts of casts, and supports and braces, and various appliances to meet the needs of the various cases.

All examinations of the injured men are made by surgeons who are trained in and are specializing in industrial surgery. They prescribe all treatments given, and keep in constant touch with the cases.

Many cases would have a much more rapid and complete recovery if physiotherapy could be instituted almost immediately following the injury. In order to get in touch with such cases, it would be necessary to have the physiotherapy department in the hospital, which so far has not seemed practical because the Commission does not maintain an industrial hospital. The patients are scattered among the various hospitals. A number of physicians, however, are now calling upon the Commission to send physiotherapy aides to the hospitals to treat their cases.

When the department was first opened the physicians were slow to give their cooperation, but now practically all physicians have come to see the benefits and are cooperating.

From seventy-five to one hundred

men are being treated daily by the Commission in its physiotherapy clinics, and while it is not possible to give exact figures showing the saving being made it is safe to say that many times the cost of the clinics is being saved by reducing the expenditures for time loss and permanent partial disabilities. Also the state is saving itself from an increasing number of permanent cripples, as hundreds of men are being restored their earning power who otherwise would be much more seriously handicapped by the results of their injuries.

After all has been done to restore a man physically, if he is still unable to return to his former employment, he is eligible for vocational retraining. During the period of training his compensation allowance is added to from the rehabilitation fund sufficiently to entirely support himself and family. The Commission also pays all cost of training, such as tuition and supplies.

These men are being retrained in the various vocational schools. If there is no school which teaches the particular trade the injured man wants, then he is placed on the job as an apprentice. In carrying on this work, the Commission has eliminated all red tape and endeavors to handle each case in as direct and simple a manner as possible. Excellent results have been obtained. Approximately 140 men have finished training and have been returned to the industries, while 40 men are now in course of training.

Minneapolis has constructed 160 courts for men and women to pitch horse shoes in 26 neighborhood parks.

A view of mechanical apparatus for forced exercises employed for the restoration of lost function.

Using arm and leg whirlpool baths preceding massage treatments in the rehabilitation of injured workmen.

Necessary Care of the Foot in Industry

Periodic Examination and Regular Daily Foot Exercises Are Essential

BY JACOB GROSSMAN, M.D., CHIEF OF THE ORTHOPEDIC CLINIC, LEBANON HOSPITAL; CHIEF OF THE ORTHOPEDIC, STUYVESANT POLYCLINIC; JUNIOR ADJUNCT ORTHOPEDIC SURGEON, LEBANON HOSPITAL, NEW YORK CITY.

THE erect attitude of man demands that the human foot shall be an organ for balancing the body in a much greater degree than in most other animals. Many of the disabilities of the foot and ankle are due to conditions disturbing its proper balance and therefore giving rise to complaints of weakness or pain from undue strain of such structures as ligaments and joint capsules, or undue pressure on bony structures and the parts covering them.

On examining the mechanism of the foot it is found to be divisible into several elements in each of which disturbances of balance with corresponding disturbances of function may occur and, when it comes to treatment, the same principles apply whether the original cause is direct trauma or some other disturbing factor.

The importance of the care of the feet cannot be overestimated. The proper fitting or adjusting of shoes, the correction of faulty habits of use, with the overcoming of elements of weakness, as well as the direction of the hygiene of the feet, are factors upon which depend the fitness for duty of large numbers of industrial workers.

The average individual wears shoes which are as small as can be used without actual discomfort. The socks worn are of such texture as to occupy but little space. Such coverings of the feet may meet the needs of some workers, especially those who pursue sedentary occupations in which the physical activities are slight. However, they are harmful and inadequate where walking and standing are required, since the action of the muscles of the feet are interfered with. Interference with proper action of the

muscles tends to weaken them. Weak foot muscles usually predispose the individuals to weak or flat feet.

Some occupations, such for example, the pursuits of salespeople, policemen, lettercarriers, or waiters, demand the hardest kind of use of the feet and, to make this possible the shoe covering should interfere the least that is possible with foot action, while there should be ample room for warm soft socks, not only to protect the feet from chafing, but to furnish an absorbent for the moisture that will be developed. Corns, both hard and soft, bunions, callosities, deformed

worn previously and with relatively narrow widths. Sizes as large as this are needed especially in the winter when the use of warmer and thicker socks is expected. The common habit of simply increasing the width of the shoe without increasing the length is to be carefully avoided since it results in added cramping of the toes and allows the feet to spread, thus increasing the potential difficulty that exists naturally.

In fitting, the individual should stand with the shoe on and there should be at least three quarters of an inch between the tip of the great toe and the end of the upper part of the shoe when the full weight is borne upon the foot.

While these precautions are important for men or women with relatively normal feet in order to lessen as much as possible the development of later weakness, it is of greater importance for the large number of individuals with weak feet, which inevitably exists.

The commonest cause of foot deformities and disabilities, as met with in industrial life, is poorly fitting conventional footwear. Of course there are other factors which tend to aggravate the symptoms, but the main cause is shoes which do not fit the foot properly. One often hears the term "breaking in the shoe," when new shoes are worn. This term is misapplied, as what really happens is that the foot is "broken

in." The foot, being more flexible than a shoe, naturally is more easily deformed. This cramping of the foot continues until the foot has assumed the shape of the shoe, at which time the shoe is said to have been "broken in." In other words, the foot is made to fit the shoe, with consequent dam-

X-ray picture of feet damaged by conventional shoes. Note the displacement and cramping of bones.

toes, blebs, and many other foot ailments could all be avoided, if careful attention were to be given to the proper fitting of shoes and socks.

It is not uncommon to find that practically all men and women need shoes that are from a size and a half to two sizes longer than had been

Bunions and hammer toes.

age to the muscles, toes, and arches.

Fortunately, in industrial life, the laborers rarely possess such disabilities and deformities. Their foot disabilities result from injuries and inflammatory processes in and about the foot. They usually wear very broad-soled shoes which also fit them properly in the length. One rarely, if ever, can see these individuals seeking relief for corns, bunions and cramped toes. We should profit from their experience and educate every one in the advantages to be gained by wearing of proper, anatomically correct footwear.

The office workers and the fashionably dressed individuals are not blessed with such good fortune. They usually wear fashionable, conventional shoes with the inevitable resulting damage to the feet and the long train of symptoms referable to it.

The feet should be examined periodically, just as are the teeth, eyes, heart and lungs, and where the indication exists, proper treatment should be instituted.

The proper precautions necessary are first, good anatomically correct shoes and second, foot exercises. These exercises should be performed regularly, for fifteen minute periods, twice a day. Bicycling, tip-toe exercises, raising the body weight while standing upon the outer borders of the feet, are very efficient ones to practise.

Where there is a tendency towards weak or flat feet, the inner borders of the soles and heels should be built somewhat thicker than the outer borders, the amount of thickening depending upon the degree of weakness present. The usual thickness that is

inserted is about three-eighths of an inch. The object of this wedge of leather is to transfer the weight of the body from the inner border of the foot to the outer border, in that way relieving the arch of the foot from undue strain. Where, in spite of the fact that proper precautions have been taken and foot pain and disability still persist, proper arch supports may have to be resorted to, before relief can be obtained.

The arch supports are made of steel and are fashioned after a plaster model, made from the foot of the patient. These arch supports must be made for each individual and should be altered from time to time so as to conform with the changes taking place under their use. They should be worn at short intervals at first, gradually increasing the length of time, as tolerance is established, when they can be worn the entire day.

In acute weak or flat feet, that is, the type in which the symptoms come on suddenly, rest in bed, followed by strapping with adhesive plaster, gives the quickest relief.

There is another type of weak or flat feet, which does not respond to the treatment just outlined. This type is known as rigid or stiff weak feet. It is one in which the arch is not only flat, but the movements of the foot are restricted. Fortunately, this type of weak foot is not as common as the flaccid or loose type. For a patient who must be returned to his work as soon as possible, because of financial and other responsibilities, the best method of treatment is to break up the stiffness under an anesthetic and applying plaster-of-Paris bandages. The bandages should be retained for a period of thirty days. After the thirty days have elapsed, the plaster bandages should be removed and impressions of the feet taken, from which the models are made. From these models the arch supports are fashioned. The feet should then be replaced in the plaster bandages until the arch supports are ready. This usually is from four days to a week later.

After the braces are ready, a good orthopedic shoe having an elevation of one-half an inch on the inner border of the soles and heels should be prescribed. It is very important to impress upon the patient that the treatment does not cease at this stage. He should still practise the exercises and if possible should have electric baking and massage for his feet. This treatment should be continued until all the movements of the feet are free and painless.

Bunions are another source of suffering and disability. They are usually associated with flat feet and usually result from wearing narrow shoes. They are deformities located in the first joint of the big toe, characterized by a deflection of the big toe, with in many instances, an enlargement of a small sac, which sac forms the bunion. The degree of deflection may vary from a very slight one to one that is so marked that the big toe may lie either over or under the second toe. In some of these latter instances the patients walk upon their big toes.

In the normal foot the toes are straight, lie flat, and can be moved downward. The inner side of the heel, the inner side of the first joint of the big toe and the inner side of the tip of the big toe lie in a straight line so that in a normal foot a ruler applied to the first two points should come in contact with the inner side of the tip of the big toe. The conventional shoe is not made to allow this relationship to exist. The inner border of the conventional shoe is not straight. It is only partially straight to a point just behind the first joint of the big toe, beyond which it curves abruptly outward to meet the outer border of the shoe. A normal foot pressed into a shoe of this type will soon assume the same shape with the consequent outward deflection of the first joint of the big toe and an inward deflection of the little toe. The skin overlying the prominence formed by the bunion is not affected in the early cases. Later it becomes inflamed and in some instances may become the site of an infection.

The symptoms of a bunion depends

Extensive callus formation on the soles of the feet.

upon the condition present. As a rule there is pain in the big toe, redness, local heat and swelling. When an infection of the bunion occurs there usually is aggravation of these symptoms plus the addition of pus.

Bunions are preventable deformities. People should be educated to wear anatomically correct shoes in preference to the conventional. They should be impressed with the dangers that may arise from forcing their feet into shoes that are too narrow for them. The writer has observed by actual measurements that the average foot is one inch wider than the shoe worn by the individual. These shoes are not only too narrow but are from one to two sizes too long.

In mild cases of bunion a proper shoe will usually prevent further development of the deformity. Exercises of the toes may prove of assistance. In some instances felt wedges placed between the first and second toes have proved of value.

When inflammation is present, the application of wet dressings for a number of days will usually overcome it. During this stage it is of advantage to pad the inflamed area with a piece of felt perforated at its center. This will protect the sore spot from further irritation of the shoe.

Strapping the toe in such a manner as to straighten it has proved of value in mild cases.

When, in spite of these precautions, the deformity continues to progress,

or in cases where a well marked deformity already exists, operative interference is necessary before one can expect a satisfactory outcome. The operation should not be performed while there is any inflammation of the bunion or the surrounding tissues. It should aim not only to correct the deformity but also to preserve motion in the first joint of the big toe.

Hammer toe is a deformity of the toe, usually the second, occasionally several, characterized by bending of the toes in a hooked manner. The prominent knuckle which results, is usually the site of painful corns.

Some individuals are born with hammer toes. The common cause however, is poorly fitting and tight shoes. Socks that are too short are also responsible for the production of hammer toes in some instances. Hammer toes are often associated with bunions and a flat anterior arch.

As a rule the patients seek relief from the pain resulting from the corns, which form on the top of and tip of the toe. Occasionally they will seek relief for cosmetic purposes. Total disability is not rare. The treatment is distinctly operative, the object of which is to straighten the bent toes.

Metatarsalgia is a painful disability of the foot due to a flattening of the anterior arch. Pain is characteristic and is usually referred to the fourth toe, occasionally to the third and the second. The pain is stabbing or burning in character. When there is a callus on the sole of the foot, pain and a burning sensation are referred to that area. Disability as the result of the deformity is not uncommon.

As this condition is commonly the result of wearing poorly fitting shoes and socks, the first thing to do is to see that anatomically correct shoes and well fitting socks are substituted, before treatment is instituted. As a rule good shoes, with exercises, will usually suffice to obtain satisfactory results. Occasionally we must resort to a support and any one which will maintain the anterior arch in its proper position will be satisfactory. For relief of the acute pain a pad of felt retained in position by adhesive plaster, will usually prove effective.

Corns, another product of improper footwear, are small localized thickenings of the skin, the peripheral part consisting of a number of layers of parallel epidermic cells, and the central portion being formed by a dense mass which presses on the papillae and the dermis and causes more or less atrophy of these structures. Not infrequently a small bursa forms be-

Padding of the feet to relieve symptoms resulting from callus on soles.

neath the center of the corn, and, if the irritation persist, inflammation and suppuration may occur in it and the condition thus produced is known as a suppurating corn. Corns are usually found on the outer side of the fifth toe and the back of the second, third and fourth toes.

The symptoms are chiefly pain, aggravated by the changes of weather and the wearing of socks and shoes. When the shoes and socks are removed, relief is usually obtained, except in cases where inflammatory processes have commenced. The pain at these times are of the throbbing, pulsating variety.

Corns usually result from shoes that are either too tight or too loose. In the former instance pressure is produced and in the latter friction. Imperfections in the socks, such as knots in the worsted or poor workmanship in the darning, are also causative factors.

Soft corns usually are found in between the toes. They result from pressure of the shoes, with retained perspiration, which is unable to escape. They are white, macerated growths.

In the treatment, absolute cleanliness of the feet must be insisted upon. The part must be kept dry and pressure on any prominent points avoided. Pointed shoes must be especially avoided. When a corn has formed, all pressure should be taken off it and not infrequently the avoidance of pressure alone is sufficient to lead to the separation of the dense core and to a complete disappearance of the trouble.

Pressure may be avoided in various

Cyst on the back of the big toe which produced a great amount of suffering which was relieved after its removal.

ways: when the corn is situated between two adjacent toes, a piece of felt inserted between them, so as to prevent pressing on one another, will relieve the pressure and so bring about a cure. In the sole, pressure is best relieved by a hollow ring-pad, the corn being made to occupy the center of the ring. The disappearance of the corn may be much accelerated by paring down the dense core with a razor, after the toe has had a prolonged soaking in hot water. In paring down the thick epidermis care must be taken not to go deep enough to injure the living tissues, because the epidermis of a corn often contains much septic material which may be introduced through the incision in the skin and lead to serious infection.

As a rule, after the source of pressure has been removed and the corn has been pared several times, it is not difficult to pick out its core with a needle, when the skin of the part will very soon resume its normal appearance if further pressure be avoided. When the corn is large, it is well after paring it to apply salicylic collodion once a day repeating the paring if necessary about once a week. If the corn is situated between the toes, care must be taken to keep the latter well apart until the collodion is thoroughly dry.

When there is a suppurating corn, the patient should be made to rest and the abscess should be opened by an incision through the center of the corn. The pus usually forms in the bursa beneath the base of the corn and, though only small in amount, may from the tension under which it is retained cause exquisite pain long before it gives rise to fluctuation or any other characteristic sign of an abscess. When the corn has been cut through and the pus let out, the relief is immediate. The entire corn which is undermined by the abscess, should then be clipped away with scissors and wet dressings applied. They should be changed frequently and continued until all acute symptoms have subsided.

Blisters on the feet are occasionally encountered. They are as a rule of little moment, especially if properly treated, but they may give rise to great inconvenience and may prevent the patient from walking. This is especially so of policemen, letter-carriers and others who must walk and stand a great deal of the time. They occur about the heel, the instep or the toes. A blister is of importance partly from the physical pain in walking caused by the irritation of exposed nerve ends and partly from the sus-

Broken needle in the region of the longitudinal arch of the foot, which produced symptoms simulating those of a "flat foot."

ceptibility to infection, lymphangitis, cellulitis, etc., that have always to be reckoned with in these cases.

The preventive treatment must not be neglected. It consists mainly in observing scrupulous cleanliness of the feet and avoiding tight or too loose shoes, or undue pressure or friction on any one particular part. A further precautionary measure, which it is well to employ is to rub the feet well with fat or tallow.

When blisters have occurred the best plan is to puncture them at their most dependent part after having washed them well in any antiseptic solution, so as to disinfect the surface. After the fluid they contain has escaped, suitable measures must be taken to prevent any further friction, so that the separated epithelium may remain in contact with the raw surface beneath and protect it against external sources of irritation. If possible, rest should be enforced. If the patient is compelled to get about, some form of hollow pad designed to keep the pressure off the blister should also be provided. When it is merely necessary to prevent the surface of the blister from being irritated by the clothes, a very useful method is to protect the affected area by means of a perforated convex celluloid shield.

Callosities are indurated, prominent yellowish portions of skin, shading off at their edges and consisting essentially of thickening of the horny layer

X-ray picture of a "spur" on the heel bone (os calcis).

of the epidermis. They are due to repeated friction and may be preceded by blisters. Relief of the pressure will lead to disappearance of the callosity, but while it lasts the callosity is often extremely painful and a bursa may form beneath it and become inflamed or suppurate.

When the callosity is causing pain, it is well to shave off as much of the thickened epidermis as possible, after softening it by prolonged soaking in water as hot as can be borne, and then to apply the salicylic collodion. This application is to be repeated night and morning. This should be combined with the use of a hollow pad to prevent pressure. The pad should overlap the thickened area for three-quarters of an inch in all directions and a hole corresponding in size to the callosity should be cut in its center. This treatment will usually lead to the disappearance of the affection.

Hypertrophy of the nails of the toes is not an uncommon cause of disability in industry. The nail is usually thickened and marked by transverse depressions, while its tip becomes unduly curved. In some individuals the nail of the great toe may assume the shape of a horn, the point of which turns over towards the sole or curves round and threatens to grow into the nail matrix or the free end of the toe. This affection often results from inflammation or injury.

When a nail that is subject to hypertrophy assumes the shape of a horn, it must be carefully pared, as otherwise its tip will grow into the matrix and cause ulceration. When the horn is very massive and dense, the entire nail and its matrix may require removal.

Contusions of the nails are often followed by separation of the nail from its beds. The usual effect of the contusion is to cause hemorrhage between the nail and the matrix. When the latter has been badly contused and blood is seen as a black mass beneath the nail, separation of the latter can sometimes be prevented by making a hole through it over the hemorrhage so as to allow the blood to escape. This is easily done by scraping with a knife until the nail is thin enough to permit of the introduction of one blade of a pair of sharp-pointed scissors. The operation is quite painless. A wet dressing should be applied to prevent the occurrence of suppuration beneath the nail.

Foreign bodies lodged beneath the nail should be removed at once, because they not only cause much pain

at the time, but are apt to lead to infection, and possibly irregular destruction of the matrix and consequent deformity of the nail. After extraction of the foreign body it is a good plan to snip away the portion of the nail beneath which it lay, with sharp-pointed scissors, and then to apply a wet dressing for twenty-four hours. Unless this is done, there is considerable danger of sepsis, as there is little chance of the septic products escaping freely should the wound suppurate.

Another condition which gives rise to a great deal of trouble is that known as lateral onychia, or as it is commonly called, from the fact that it exclusively affects the toe, "ingrowing toe-nail." In this condition there is inflammation of the matrix and the skin at the side of the nail, generally on the outer side of the great toe. It usually occurs in young adults of the working class, who have much walking to do, who do not keep the feet clean, who wear badly fitting shoes and cut the great toe nail so short that it does not project beyond the soft parts. The result is that the nail is pressed down and irritates the lateral fissure or, what comes to the same thing, the soft parts of the toe are pressed up against the nail. Hence the affection, as a rule, occurs near the free end of the nail. It begins with slight pain and swelling, which impede walking. Ulceration soon occurs and spreads backwards along the lateral groove. In bad cases the supuration is abundant and fetid; there is a good deal of swelling and the granulations are exuberant. The condition is often serious on account of the pain and lameness it induces and also on account of the risk of lymphangitis.

The treatment will vary according to the stage of the disease, but in all cases what may be termed the hygiene of the foot should be carefully attended to. The nails should be cut square and their edges should project slightly beyond the soft parts. The feet should be kept clean, the socks changed frequently and the patient should wear anatomically correct shoes. If the case is seen before any ulceration has occurred, it sometimes suffices to introduce a minute pad of cotton between the nail and the lateral groove so as to take off the pressure of the edge of the nail, the other points in the hygiene of the foot being carefully attended to. This procedure is most likely to succeed when the nail is thick and well developed. When it is thin and papery it is of little use. If the ulceration has

The ordinary conventional shoe. Note the abnormal attitude of the feet.

taken place, however, this plan will not suffice.

In the later stages, various other methods are resorted to, but all, with one exception, are more or less ineffectual. This one is an operation, the object of which is to remove part of the nail and destroy the matrix, so that the nail does not grow back again.

Injuries and strains about the insertion of the heel cord are marked by pain about the back of the heel which is aggravated by walking and relieved by rest, but the pain recurs if the patient is tempted to take exercise. The condition may be divided into three types:

Tenosynovitis in which there is swelling due to effusion within the tendon sheath. This swelling extends some distance up the tendon and is both palpable and visible.

The treatment is counter-irritation, firm bandaging and rest. When the acute stage is past, the patient may be allowed to walk limited distances with the heel of the shoe raised three-quarters of an inch, so as to relax the tendon and diminish the strain. If the condition tends to become chronic, the actual cautery may be used with great benefit.

The second type is an inflammation of the bursa under the insertion of the tendon into the heel bone (os calcis). This is diagnosed by localizing the

A—Conventional shoe with a French heel. B—Good orthopedic shoe. Note expansion back. Very convenient for people with swelling of the lower limbs.

tenderness at the site of the bursa and by detecting a small area of fluctuation.

The treatment consists of relaxing the tendon by raising the heel of the shoe three-quarters of an inch. Apply a band of strapping round the leg above the malleoli to act like the wristlet worn by workmen who have strained a tendon at the wrist. The patient should be instructed to walk a little every day, but should not be allowed to do an indefinite amount of walking.

The third type is a periostitis at the insertion of the heel cord, due to strain of the insertion.

The diagnosis is made by localizing the tenderness on pressure a little lower down than in the case of bursitis and by the absence of deep fluctuation in the bursa beneath the tendon. Treatment by rest is the same as for the preceding condition.

Both these last mentioned conditions may be present simultaneously and become chronic. The best treatment then is first to puncture the bursa or the inflamed area of the periosteum several times with a hot needle.

Irregular fibrous masses are sometimes noted in the heel cord. These are usually the result of partial ruptures and if large and persistently painful they should be removed.

Spurs of bone under the heel bone running forward into the plantar fascia or short muscles of the foot are frequently seen. They often cause no symptoms. On the other hand, if the patient accidentally jumps on to a stone and bruises the periosteum over one of these spurs it may become enlarged or a bursa may develop under it. After this, the patient feels pain every time he puts his heel on the ground.

The proper treatment is to remove the spur and tissue around it to make sure of clearing out the bursa and any chronically inflamed periosteum. If for any reason operative interference should be delayed then a felt pad applied to the heel will usually give temporary relief.

Osteitis and periostitis of the heel bone often arise from bruising of the bone by a jump or a fall from a height. There may be no gross fracture, only some crumbling of the lamellae, which may be seen in a good x-ray. When a fracture occurs, the disability is often due to bony irregularities on the under surface of the bone.

Treatment is often unsatisfactory and if the bony masses are felt in the sole under the heel they should be removed. Palliative measures are of no use.

The foot is often the seat of injury. The injury may either damage the soft parts or the bones.

An overstretching or a sudden descent from a height on to the sole may lead to a rupture of a portion of the plantar fascia. The injury is accompanied by great pain at the time. Occasionally imperfect union of the ruptured fascia may lead to much pain and tenderness whenever the patient bears his weight upon the foot.

The main object in the treatment must be complete rest, so as to allow the ruptured fibres to unite. When the plantar fascia has been ruptured, the foot should be put up in plaster of Paris, with the instep fully arched by bending the toes downwards, so as to relax the fascia as much as possible. The plaster casing should be kept on for two weeks. If it is kept on too long, the fascia is apt to contract and there may be difficulty in obtaining free extension of the foot afterwards. When the plaster has been removed, care must be taken to prevent any sudden strain or great weight being thrown upon the arch of the instep for some time. Massage is useful.

Contusion of the muscles of the foot may sometimes give rise to considerable mischief. A contusion leads to infiltration of blood among the muscle fibres, which interferes with their action and often causes temporary paralysis. When struck, the muscle contracts, following which there may be fibrillary twitchings, after which the muscle relaxes and may not recover its power for two or three days. When permanent paralysis of a muscle follows a blow, it is usually due to damage to its nerve supply rather than to injury of the muscle fibres themselves.

Hemorrhage into a muscle may be followed by various troubles: there may be adhesion of the muscular fibres to each other, or fibrosis and consequent impairment of function. In some cases calcareous salts are deposited in the muscle and calcification occurs; in others a true ossification occurs. Occasionally the effused blood is neither absorbed nor organized, but becomes encysted and forms a blood-cyst in the substance of the muscle.

The part should be placed completely at rest until the hemorrhage has ceased; when this has occurred, attempts are made to get rid of the effused blood as rapidly as possible by the employment of suitable massage. Massage should consist at first, of gentle rubbing in the upward direction for twenty minutes at a time,

twice a day. In a few days the other method employed by masseurs for breaking up the exudation may also be used. Each sitting should be gradually lengthened up to half or three-quarters of an hour at a time, and the massage should be persisted in for at least two or three weeks.

When the effusion is large and does not become absorbed readily, the best plan is to make a curved incision over one side of the swelling, expose the muscle, turn out the clots and put in a drainage tube for two or three days. Massage and manipulations should be employed as soon as the wound has healed.

Incised wounds of the muscles of the foot are of no particular moment

A very good orthopedic shoe for women.

unless the incision is transverse to the direction of the muscle fibres.

Punctured wounds over muscles often do not injure the muscle, as it contracts and slides out of the way, but occasionally some of the fibres are divided and retract and leave an irregular gap in the muscle. When the incision is large and, particularly, when it is transverse to the direction of the muscle fibres, considerable retraction takes place and serious functional disability may result unless means be taken to restore the continuity of the muscle.

When a muscle has been divided transversely through the greater part of its width, an attempt must be made to approximate the divided ends by means of sutures. A drainage tube should be inserted and the limb placed upon a splint in the position that ensures full relaxation of the muscle.

Full muscular relaxation should be maintained for three days and then may be diminished daily until, in the course of two weeks, the muscle is placed fully upon the stretch. It is important not to keep the muscle in the fully relaxed position too long, because a certain amount of adhesion is likely to form between the line of suture and the tissues around and if possible, this should occur when the muscle is fully extended. The muscular contractions will then pull upon and gradually stretch the adhesions. The patient should move the muscle voluntarily in about four weeks, but up till then only passive movement should be resorted to. If firm adhesions should form between the line of union in the muscle and the other soft parts, massage and faradism are of great assistance in breaking them up. If necessary, they may be divided with a tenotomy knife.

Rupture of a muscle may occur without an external wound and results from violent, irregular or incoordinated movement. An actual rupture of muscle is much less common than is rupture of a tendon. It generally occurs in men and is usually partial. In the foot the muscles most commonly ruptured are the plantaris and the heel cord. The symptoms accompanying the accident are sudden pain in the part, with a sensation of tearing, followed by loss of power in the affected muscle. There is a characteristic depression over the seat of rupture and a swelling immediately above it, due to retraction of the upper part of the muscle.

There are two methods of treatment, viz., suture of the torn muscle fibres or an attempt to obtain healing without operation.

The non-operative treatment consists of strapping the limb from the balls of the toes to just below the knee. The strapping is kept on for three to four weeks, being renewed when necessary. Massage should be given after the strapping is removed.

Occasionally a tendon may be displaced from its normal site. The tendon most liable to displacement from violence is the peroneus longus at the outer ankle. This condition is important as it gives rise to much disability. It usually results from the patient trying to regain his balance. A sudden forcible movement when the foot is everted, such as occurs in a fall in which the foot suddenly reaches the ground in an everted position, is very apt to dislocate the tendon from its groove.

When the accident occurs there is

a sensation of tearing, accompanied by sudden pain and a certain amount of loss of power in the foot. Very often too, there is a subfascial hemorrhage and considerable swelling, so that, unless the case is seen very early, the exact injury cannot be diagnosed until two or three weeks have elapsed. It is then found that a tendon which ought not to be there rolls under the finger on the outer side of the ankle.

The treatment consists in replacing the tendon in its groove and keeping it there by artificial means until the tear in the sheath has mended. This may be done either by replacing it by manipulation and afterwards fixing the foot in the inverted position, or by means of operation. Without operation it is very difficult to replace the tendon satisfactorily and to maintain it properly. As considerable swelling generally follows the injury, it may readily slip out again and the displacement not recognized until the swelling subsides some weeks later. Hence immediate operation is the best procedure.

When no operation is thought desirable or when the patient will not consent to one, apparatus must be resorted to. The tendon is readily replaced in the early stage by flexing and everting the foot and pressing the tendon into the groove. The foot is then strongly inverted and brought nearly to a right angle. A firm pad is fixed over the groove so as to prevent the tendon from escaping, and an external moulded splint applied so as to fix the ankle joint. The splint should not be taken off for about six weeks, except for passive motion and then the foot and ankle should be strapped for some time. The patient should be cautioned to walk about with the foot inverted.

Fracture of the bones of the foot occur quite often in industrial life.

Fracture of the astragalus alone is of extreme rarity. The fracture results from falls from a height upon the foot. The bone may then fracture or become dislocated. If it fractures, the anterior part of the bone is displaced forward, the fracture being through its neck.

The treatment is difficult and will depend upon the condition of the astragalus as shown by the x-ray. In most cases it would probably be advisable to expose the fractured bone and in the majority of instances it would seem desirable to excise the astragalus completely. The movement of the ankle after removal of the astragalus is remarkably good, whereas if a piece of bone is left in the

joint, a satisfactory result can hardly be expected.

The most common fracture in the foot is that of the os calcis, which may occur from falls from a height upon the heel or from the foot being run over. The result is comminution of the upper part of the os calcis. The posterior portion, to which the heel cord is attached, may be broken off.

Many of these cases are overlooked and are treated as mere sprains. The mistake is of importance as these fractures are liable to leave much stiffness.

When there is an extensive comminuted fracture of the os calcis the heel feels like a bag of bones and it is difficult to bring the parts into good

Bottom view of a good orthopedic shoe. Note anatomically correct shape of the sole with its straight inner border.

position. The best plan is to divide the tendo Achillis and then to hold the heel in position while the patient is under an anesthetic and to apply a plaster of Paris casing so moulded as to bring the heel and the os calcis into proper shape. In these cases any resulting disability will be in connection with the transverse tarsal joint. Special care should be taken to prevent occurrence of a valgus condition.

Fracture of the other tarsal bones are comparatively rare, except as a result of a general smash of the foot. As they are usually compound and associated with extensive injury, they do not call for individual description.

Fractures of the metatarsal bones may be caused by run-over injuries or kicks, or heavy weights falling upon the foot. As a rule there is little displacement in these fractures, the other bones forming splints for the fractured one. All that is necessary is to see that the broken ends are brought into position by suitable manipulation and then to fix the foot in plaster of Paris bandages.

In concluding the writer would emphasize the following points.

- (1) All employees should have their feet examined periodically.
- (2) Foot exercises, proper orthopedic shoes and hosiery should be prescribed as preventive measures.
- (3) The feet should be protected against dampness and cold, by wearing of woolen socks and rubbers. These should be insisted upon for out of door workers. It is an excellent way to prevent frost bite of the toes.
- (4) Injuries of the foot should receive prompt attention. Proper diagnosis and treatment is essential, so as to return the worker to usefulness as soon as possible and in as normal a condition as is possible.
- (5) Proper hygiene of the foot should be practised.
- (6) Patients should not be returned too soon to their occupations, as haste makes for waste, in a majority of these cases. Returning to work before healing has been complete will only tend to aggravate the pathological condition present and in that way prolong invalidism.
- (7) Institution of these simple precautions as regard to the care of the foot in the various industries would tend to keep suffering, loss of time and invalidism at a minimum.

The proposal of a prominent English jurist to give deadly poisons a distinctive color as a safeguard against mistakes is taking definite form, according to the London correspondent of the *Journal of the American Medical Association*. The privy council has asked the general medical council to express its opinion on the proposal that strychnin should contain enough "brilliant green" to make it readily recognizable. It is further proposed to add suitable dyes to arsenical poisons "sheep dip" and "weed killer" so that, if they should be administered for homicidal purposes the dye would be deposited in the body of the victim.

Dutch Labor Legislation*

BY J. G. C. VOLMER, PROFESSOR OF BUSINESS ADMINISTRATION, UNIVERSITY OF DELPH, HOLLAND.

THE regulations in Dutch labor legislation which have to do with the prevention of excessive fatigue, are to be found principally in the regulations based on the Safety Act of 1895 and in those based on the Factory and Workshop Act of 1919.

Safety Act

The regulations on the basis of the Safety Act apply to practically all factories and workshops. They give very detailed regulations for the following items:

- (1) The height of the workrooms and specifications for the number of cubic meters of air which must be available for each workman.
- (2) Lighting (30 Hefner candles at 1 m. distance).
- (3) Fire prevention.
- (4) Prevention of accidents in case of fire.
- (5) Canteens and clothes rooms (cleanliness, ventilation, and humidity of work rooms).
- (6) Water closets.

For all these subjects very detailed regulations, expressed in figures are given, *e.g.*, the height of undetrimental workrooms must be at least three meters; and for each workman seven cubic meters air must be available, etc.

In detrimental workrooms, *e.g.*, in those where the air is vitiated by dust (phosphate milling, bronzing, etc.) this amount is increased to twenty cubic meters.

The inspectors of factories and workshops have power to give detailed orders, on the basis of the Safety Act, for the following items:—

- (1) Promotion of cleanliness.
- (2) Maintenance of good temperature and sufficient ventilation without draught.
- (3) Dust prevention.
- (4) Protection of machinery and electrical apparatus, etc.
- (5) Prevention of poisoning, infection and industrial diseases.

The inspectors of factories have moreover the right to fix distinct limits of the time during which a workman may remain in excessive temperature, noxious gases or dust (cleaning of boilers), etc.

On the basis of these regulations the labor inspectors exercise continu-

ous control. Gradually they have arrived at a certain standard practice.

The Factory and Workshop Act gives a general limitation of the time of labor of eight and one-half hours per day and forty-eight hours per week and gives as a general regulation that no night labor is to be performed between 6 p. m. and 7 a. m.

In the regulations based upon this Act special provisions have been made for the safety and general well being of women and adolescents.

The legal medical examination of young people for all detrimental trades, is of predominant interest. Without a medical approval, persons younger than eighteen years of age are not admitted to the trade. This applies to important branches of industry, such as the printing industry, the diamond cutting and polishing industry, textiles and cigar making, and to all workshops using lead.

Through this measure the basis has been laid for a rational vocational selection on physical criteria, which must proceed a further psychological analysis.

Some Dangerous Trades

PROGRESS in industrial medicine has lagged wherever preventable occupational disease has not become a compensable charge against the industry causing it, and trades dangerous to workmen remain uncontrolled because almost everywhere the facilities are lacking for the detection and observation of industrial disease. Not more than four or five places in the United States afford opportunities for research in industrial diseases, and less than ten hospitals throughout the land have sufficiently complete records for the research student to trace cause and effect in sickness and working environment. A small group of men in Chicago were pioneers in this work. Ohio is alive to the exigencies of the industrial situation. The Massachusetts General Hospital is prosecuting precise studies on these subjects, and Johns Hopkins covers the field; but for the most part in communities, industrial and otherwise, little curiosity is evinced in the subject and no consistent inquiry is made.

Recent progress in industrial medicine was the burden of a lecture on

Further regulations for the detrimental trades are: the providing of sanitary accommodation, *e.g.*, washbasins, soap, nail-brushes, towels, etc.

In principle this Labor Act has already existed for thirty years and has gradually been extended. In the very beginning it was only applied to labor in factories and workshops. With the last revision in 1919 it has been extended to offices, shops, chemist's shops and to people occupied in art and entertaining. For shops, chemist's shops, and dressingrooms of theaters, etc. suitable sitting-accommodation regulations have been given. The number of seats must at least be just as large as the number of women or adolescent people who work together at a certain time. People must be given the opportunity to make use of these seats whenever this is possible with a view to the work to be done.

The Labor Act, moreover, opens the opportunity to prohibit an unfavorable wage system, for adolescents as well as for adults. Up till now, however, this regulation only applied to children under fifteen years of age. They are not allowed to work in any piece-rate system, unless the Inspector of Labor has given special permission. As a rule, however, this special permission is not given.

dangerous trades given before the Chicago Social Workers' Club by Dr. Alice Hamilton on April 2. There are no old truths on the subject, said Dr. Hamilton. The newer studies in this field, and what has been found out in the last five years represent the sum total of practical achievement. Industrial medicine was fortunate that the first significant industrial hygiene inquiry in this country was on phosphorus poisoning, a disease whose ghastly ravages were spectacular, easily identified with the trade process causing it, and to be eradicated by so simple measures of workplace control. The law that led to its eradication was unconstitutional, but, fortunately, we did not know it. The company which possessed the formula of the innocuous process utilizing sesquisulphid waived its exclusive rights, and the situation was controlled. Manganese poisoning is a newer problem.

A much more complicated situation exists in the study of fatigue. Much labor has been expended in the perfectly futile search for a simple and satisfactory test for the detection of

*Paper delivered before the International Committee for the Elimination of Unnecessary Fatigue of the Society of Industrial Engineers.

dangerous degrees of industrial fatigue. British researches have covered a period of three years, and American studies two years, with the result that the most that can be said is that in heavy work cutting down hours appears to increase the possible output. This does not apply in lighter trades, but recent studies go to show that little real work is accomplished in the last hour of a twelve-hour day. Reynold Spaeth has issued the dictum that the subjective feelings of the workmen are still the best indication of fatigue. Dr. Hamilton ventured that not fatigue toxins but delayed responses are the danger signals, and that not until our observations carry the same group over long periods, and some basis is gained for detecting long-range effects of the strain of overwork can we hope to know what undue stress does to the health, longevity, and continued effectiveness of the worker.

Notions that all dusts are deadly have undergone recent change on the demonstration that some dusts are always dangerous, some are apparently always harmless, and certain trades always show a high tuberculosis rate independent of dust. It is demonstrable that the dusts proved to be dangerous all have the common quality of containing free silica, and such trades as sand blasting, glazing, enameling, glass-making by fusing, and natural emery polishing are the ones wherein dust constitutes the hygienic problem. The same test explains why the mining of certain ores is attended with the greater relative danger. In Arizona, where the copper is mingled with porphyry, with silicates, respiratory diseases are highly prevalent, while in Butte, Mont., the U. S. Public Health Service found tuberculosis in 432 of 1,018 miners examined. In the Granite industry of Vermont, Baldwin found the tuberculosis rate was 90.6 per 100,000, and Lanza found 15 per cent of all zinc miners in Joplin affected. Comparisons made between wet and dry grinding processes showed wet grinding harder of air control than the dry process, and the incidence of respiratory affections as great.

Studies of the dust itself are interesting. It is only the particles not more than two or three microns in length that find lodgement in the lungs and cause the trouble. Reliance upon respirators to protect against the danger serve only to ease the employers' conscience. It is the chemical, not the physical characteristics that count. The phagocytes in the blood are not able to deal with particles of

silicate. Once such material is ingested, the phagocyte does not find its way again into the blood and carry off the particle, but stays right there, to become the focus of future infection. Silica, therefore, is dangerous while coal dust is not.

Many kinds of dusts remain to be studied. It is not known, for instance what is the remote effect of lint from cotton, jute, or silk. Fur cutters and workers in felt hats seem to be no more prone to lung trouble than the general population. The mortality of textile towns, however, is frightful. This may be similar to the printer's trades and to shoe manufacturers, where the difference between the tuberculosis rate in workers and non-workers is related less to atmospheric conditions *per se* than to low wages, immaturity of workers, speeding up, and heat and humidity in work places.

The danger to workers from such poisons as lead is directly related to the process and the manner of handling. The safe lead industries are precisely the ones which are taking precautions. Lead is always a poison. The roasting of oxides, the fumes that rise from molten lead, are particularly dangerous. Brass dust is dangerous because of its lead content.

Another danger, increasingly various and more and more prevalent arises from the solvents in the rubber industry, in shellac and varnish, and in dry cleaning the solvents of fats. Denatured alcohol is not without its danger. Blindness has resulted from as low as 4 per cent. The most important of the newer poisons is benzol, which causes the blood to deteriorate and the blood-renewing bone marrow to cease functioning. Not only the red blood suffers, but the white corpuscles disintegrate, resulting in the aplastic anemia which, especially in young girls, is so often fatal. The chlorin derivatives are another ever present danger and new solvents are appearing almost constantly which call for observation.

With wider knowledge of these subjects more attention and better protection will be given to the dangerous trades in which they are involved. Industries which now pay meticulous attention to infections in cuts will then take the simple precautions necessary to obviate occupational disease. The most promising solution for the extension of safeguards of this kind is in the way of compensation laws which bring occupational disease under the same system which now protects the workmen against accident. That will mean the development everywhere of the system so effectual in

Pennsylvania of consultation by experts for the detection of dangerous trades. A body of impartial figures will be developed, and the scientific curiosity of trained men will be directed toward the solution of the difficulty.

California Industrial Accident Commission Report

The outstanding fact in the annual report of the Industrial Accident Commission of the State of California, as submitted to Governor William D. Stephens, is that there was a decrease of 42 industrial deaths in 1921 as compared to 1920, the total respectively being 550 and 592. The statistics further show a reduction of 38.39 per cent in the industrial death rate of California for the calendar years 1914 to 1921, inclusive.

There were 1,643 permanent injuries reported in 1921 to the commission, as compared to 1929 in 1920. There was also a reduction in temporary injuries, as shown by the totals of 123,336 in 1921 and 131,587 in 1920. In 1921 temporary injuries to the total of 60,685 did not cause loss of time from work.

Out of the 550 deaths last year there were 453 compensable, and the remaining ninety-seven did not come under the commission's jurisdiction. The record shows that 114 were caused by varied classifications; ninety-eight by railroad, vessel and stevedoring operations; ninety by construction; seventy-eight by manufacturing; seventy-one by public utilities; fifty-three by mining, quarrying and oil producing; forty-six by agriculture. There were five women killed while at work in 1921; the similar total in 1920 was three.

Total dependents to the number of 701 resulted from 302 fatalities, 117 partial dependents were left in fifty-nine cases, in 159 cases there were no dependents, and in 30 cases the degree of dependency was unknown. The average age of the widows was 38.7 years. The dependent children averaged 8.8 years.

Life pensions were awarded in nine cases of serious and permanent injuries. There were sixteen such injuries in 1920. Injuries that caused time loss of over seven days numbered 32,286. The statistical department's report show that in 1921 there were 237 permanent eye injuries, twenty-seven arms amputated, 658 fingers lost, twenty three legs or feet lost, and sixty toe amputations.

Occupational diseases number 576 in 1921, as compared with 596 in 1920.

Dust Removal Equipment

THERE is very little doubt that the number of deaths each year which are due to lack of protection for operators of polishing and grinding wheels runs into the thousands; and permanent disabilities such as lost eyes, weakened lungs, etc., add further to the damage toll of unguarded wheels.

Studebaker Corporation show the equipment used in polishing and grinding departments. Information from C. A. Lippincott, manager of the cooperative department, states that in the machine shop polishing department this equipment includes a blower operated by a thirty horsepower motor, which takes the dust from ten

horizontal section of the "T" is tapering in form, having a diameter of nine and one-half inches at the small end and a diameter of fifteen inches at the approach to the vertical section. This vertical section, which leads to the fan overhead, is twenty-four inches in diameter and approximately fourteen feet in length. The motor and blower are located just under the roof of the building. A speed of 870 R.P.M. is attained by the motor.

The employees are appreciative of this equipment. One man who has had twenty years experience covering work in more than eighty shops, says that this protective equipment is about as good as he has ever seen.

The polishing wheel guards are adjustable, so that as the wheels wear down the guard may be adjusted in accordance with the reduced size, in order to give complete protection at all times.

In the grinding room of the tool department adjustable dust collectors are used, with flexible connections so that the collectors may be adjusted to various types of work. A much smaller motor is used to operate the blower as there is not so much dust to be carried off. The sparks, emery dust, etc., are carried to the roof, as in the

Polishing lathes at the Studebaker Corporation's South Bend Plants. Picture shows adjustable guards and "T" type blower pipe leading to fan overhead.

The danger in connection with grinding comes from the flying sparks and dust, the latter especially when the wheel is being "dressed." In the polishing operations the dust is the factor which causes the trouble. Flying sparks from grinding wheels are a frequent cause of serious eye injuries. These can be partially prevented by the use of goggles, though it is indeed difficult to get men to wear goggles continuously, and the best goggles are bound to admit some particles of dust, in spite of careful design and fitting. Furthermore, the men are urged to "get production" and they cannot work quite as fast with goggles as they can without, and there you are.

So, for the sake of more continuous production and for the sake of the reduction in labor turnover which comes as a result of better working conditions, if not for the sake of the man himself, it is highly important that the grinding and polishing operations in industrial plants be made safe for the worker.

The accompanying photographs, taken at the South Bend works of The

View in grinding room of Tool Department, The Studebaker Corporation, South Bend Plant. Photograph shows dust collectors with adjustable connections.

double head polishing lathes. The dust conveyor consists of horizontal pipes connecting the wheels with the blower pipe which is in the form of a "T" as shown in the illustration. The

case of the polishing department blower. The details of the plan have been worked out by competent ventilation engineers and are highly effectual in handling the hazard of dust.

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Columbus Opportunity School

By BERTHA W. EISENBEIS, PRINCIPAL, OPPORTUNITY SCHOOL, COLUMBUS, OHIO.

THE Opportunity School at Columbus, Ohio, grew out of a disciplinary school for boys. Boys were sent to this "Special School" charged with all the sins of the decalogue and probably guilty of them, too. At first I was certain that original sin was the enemy I was fighting and with all the optimism of youth I fought him tooth and toe-nail. By the close of ten years' experience, of "wrestling" with the devil, I found I was tilting with wind-mills. In my blind way I began to feel that there was a screw loose somewhere in the make-up of these boys transferred to my school.

About this time the department of educational psychology at the Ohio State University became active in administering mental tests. All were fish for their nets and so we were examined. The results were very enlightening. The burden of blame was removed and a new deeper note of sympathy born of understanding took its place.

First of all, ideas of concrete results were pushed very far into the background. Naturally this brought the individual child forward as nothing else would have done. "Happiness First" became our motto. The establishment of happiness prepares the ground for the growth of self respect—not egotism or self love but good wholesome self respect resting upon a foundation of truth toward personal achievement and conduct. To build thus the child must be able to achieve something. He must accomplish some task with success so that in the community of his fellows he can point with pride at some result of his efforts. What this task is—is of small matter. Polishing a stove, scrubbing a floor, washing dishes, setting a table, cleaning a window, sewing, caning

a chair, raising a garden, painting a picture, extracting a square root—all are of equal merit if well performed. How much the health of the world's soul depends upon menial tasks well done!

"Nothing is good or great alone
All are needed by each one."

This we saw clearly was our program. Of course to carry out this program it is necessary to study the individual ability of the child. And

this is our utmost endeavor. Not that we hope to make carpenters, brick masons, cement layers, etc. of these children, but to find that contact to which each individually will respond by growth. Growth not necessarily toward intellectual attainment but growth toward self respecting American citizenship.

Matters have progressed in Columbus since those Ohio State pioneers journeyed to town and helped us with our first inquiry into the mental realms of our children; and today we have at our disposal not only the services of the Ohio State University but those of the Ohio Bureau of Juvenile Research also. These facilities give us a fine free start.

When a child comes to Opportunity School he enters an academic class where he remains for two weeks before he is placed in any shop. This is for the purpose of making friends with the child so that we may have some idea of his inclinations. By slow degrees he is introduced to the life of the school and shyness and embarrassment are overcome. The other children become used to him and he is not subjected to the cruel comments of frank childhood when he makes his first essay at new tasks. This initial period over, his real work begins.

As to the balance between academic work and hand work, the theory is one of fifty-fifty. In force it becomes a sliding scale. One child may carry a program of three-fourths academic and one-fourth hand work—the maximum academic program in the school; and the next entrant may be fitted out with three-fourths hand work and one-fourth academic—the maximum hand work program. There are cases where it would be wise to drop even this minimum academic course but many reasons deter us. Parental ob-

These girls make their own dresses and hats. Personal pride and the stimulus of the "my" feeling is so engendered.

Interested occupation is the effective disciplinary measure in the Opportunity School.

jection—the value the public places on academic attainment are two important reasons for retaining this small amount.

Where a child will voice no preference it falls to the school to begin a course of trying out. I should like to say right here that there is no such thing as too great an effort for this inquiry. Its result is the most crucial test in the education of the child. One cannot be too cocksure of their own judgment in giving this test. I am reminded of a huge brawny black boy that came to me, and looking at him I immediately began to yearn for miles of cement walk to lay or for innumerable unconquered coal piles. You will smile when I inform you that I later found his contact to be embroidery. A needle and not a pick was his medium of expression.

Toward this inquiry the Opportunity School offers the following lines of work. For boys—bench work, cement work, chair caning, brick laying, clay modeling, elementary metal work, cooking, sewing, janitor service, gardening, refinishing, repair of furniture, shoe cobbling, barbering, or any line of work that the child himself might suggest, provided of course it is feasible.

To our girls is open the same work with the addition of dress making, millinery, costume designing, interior decorating. The nurse gives a simple course in care of babies and in home nursing and personal hygiene.

Both boys and girls flood the classes in folk dancing and gymnastics.

Our orchestra of forty pieces and a monthly newspaper are among our achievements. Our toys are in great demand by Columbus merchants. It is our good fortune to always have one or two doll houses to build and

furnish at Christmas time.

Our girls cook and serve a lunch every day for teachers and pupils, handling as many as fifty lunches per day. Lunch is served to the children for five cents. We give nothing. Lunch, service in the cobbling shop, the barber shop, clothes etc., all must be paid for. That no one need be held from what he needs we have innumerable small tasks about the school that we apportion as the need arises. By this we hope to establish clearly the relation between supplies and labor. Do you need a pair of shoes or a hair cut? Well, hunt a job!

A washing and an ironing is done every day on the grounds. Girls usually do this but under stress of other work the boys help voluntarily. I often wonder what many mothers would think were they to see how popular a pastime dish washing is among the boys.

Service in our dining room has

proved a source of income for several girls during the last two vacations.

Two boys last summer established a furniture repair shop and made good. Our girls are easily placed as maids and we endeavor to show them the value of this work over factory work.

"He is happy who enjoys his work" is a sentiment that we drive home hard. Work—work—work—and then more work—happy blessed work is the burden of our song and it is a tune that we have no difficulty in getting our boys and girls to swell.

Our fear is not that we will not have a school but that that school will not touch life. So we seize every opportunity to really do something human. Hence when the Washington's pride of fourteen summers succumbed to tuberculosis and money was short for the funeral, our girls laid aside their regular work and fashioned a shroud. When the Mareno family increased—what better chance to show our knowledge of a simple layette! When the Pegdon family was burned out there was the opening for our furniture repairers to come to the front.

The most precious things of life lie at our hand for the reaching—not riches, but work well done gives rest and peace.

The best school, in the best city, in the best country in the world. Opportunity School, Columbus, O.

We Believe in the Constitution of the United States.

The principal effort of the division of research extension of the National Research Council for the coming year is announced to be the raising of funds in sufficient amount to permit intensive work on the tables of physical and chemical constants which is being edited by the Council.

The boys separated for disciplinary control are not only trained for work, but find restoration through pure fun.

The Chronic Disabled Patient

Extent of Problem and Cost of Their Institutional Care in New York City

BY HAVEN EMERSON, M.D., CHAIRMAN, EXECUTIVE COMMITTEE, ASSOCIATION FOR THE PREVENTION AND RELIEF OF HEART DISEASE, NEW YORK CITY, N. Y.

THROUGH the generosity of the Sturgis Research Fund, a study of the problem of the chronic cardiac patient has been undertaken by the New York Association for the Prevention and Relief of Heart Disease. A knowledge of existing facilities, and the extent to which they are used, or are inadequate is a necessary preliminary to the preparation of a policy.

What percentage of the service of general hospitals is devoted to heart disease patients? What is the annual cost of the facilities now offered? How far short of recognized needs do the existing medical and social services fall?

To answer these specific questions facts were obtained from ten large general hospitals, from all the dispensaries where special heart classes are maintained, and from those convalescent homes which accept patients recovering from heart diseases. In each instance the institution studied was visited, and the facts here reported were obtained at first hand from the records by a representative of the executive office of the Association.

Hospital Care

The records of ten hospitals were studied: (1) Bellevue Hospital; (2) four hospitals of the Department

of Public Welfare—Kings County, Metropolitan, City, and Central Neurological; and (3) five of the large privately supported hospitals—New York, Presbyterian, St. Luke's, Mt. Sinai, and Montefiore Hospital and Home.

General Hospital Patients

The facts collected for the twelve months of 1920 or 1921 (see Table I) may be summarized as follows: Of the total number (98,838) of patients

admitted to these ten hospitals in twelve months, 4,522, or 4.53 per cent, were recorded as suffering from one or more of the following cardiovascular conditions, either as chief cause of disability or as an important complication (Table II): chronic valvular heart disease, myocarditis, aneurysm of aorta, endocarditis, pericarditis, angina pectoris, cardiac hypertrophy, and cardiac arrhythmia. The ratio of cardiacs to all patients admitted varied from slightly less

than 2 per cent in the case of Bellevue Hospital to 9.2 per cent at Montefiore Hospital and Home, and 49.6 per cent at the Central Neurological Hospital, the ratio of the latter two hospitals being affected by the fact that they accept chronic and apparently permanently disabled cardiac patients.

Sex and Age of Patients

Of these 4,522 cardiac patients, 2,468, or 54.58 per cent were males, and 2,054, or 45.42 per cent, were females. The age and sex distribution is graphically portrayed in Chart I.

Occupations of Patients

In spite of the lack of sufficiently exact description of the details of occupations of these patients, Table III is of interest to those concerned with the occupational guidance and vocational training of persons in whom a cardiac lesion has already been noted, though not yet disabling to the point of occupational handicap. The possible occupational element in causation of disability from heart disease can, by no means, be estimated from these tables, as the number of people employed, and the length of employment in the respective trades and occupations listed are not known for the community as a whole. Of the 3,027 patients for whom the records were sufficiently complete to quote, occupational data are as follows: housework, 928; school attendants, 259; labor (not specified as to variety, length or condition of work), 251; clerks, 77; cooks, 58; porters, 39; carpenters, 36; seamstresses, 20; seamen, 20; laundresses, 16; salesmen, 16; firemen, 15; pressers, 14; hospital helpers, 12; chauffeurs, 11; operators,

9; painters, 33; tailors, 32; watchmen, 32; waiters, 22; farmers, 8; and cigar makers, 8.

Results of Hospital Care

Of the 4,502 cases in which the records were complete, the condition on termination of hospital care in 2,298, or 51.04 per cent, was reported as improved, and in 565, or 12.55 per cent, unimproved; 1,639 or 36.4 per cent cases terminated in death.

Of the total of days hospital care provided for all patients at these 10 hospitals during the 12 months of the study, 2,525,233, the days of care for cardiac patients were 236,047, or 9.35% of all patient days given at these hospitals in the year of record.

The common knowledge that cardiacs are apt to require long periods of hospital bed care is emphasized by the fact that cardiacs, though representing only 4.58 per cent of all patients, required 9.35 per cent of all days of bed care provided by these hospitals. The average duration of hospital care on each admission of these heart patients was between twenty and forty days.

At the Central Neurological Hospital of the Department of Public Welfare, and at the Montefiore Hospital and Home, where alone among the ten hospitals chronic disabled cardiac patients were regularly accepted, the average stay was of course much larger, the average being, for the former 140.6 days, and for the latter 253.8 days per patient.

Hospital	Average days of care
Bellevue	20.2
Kings County	25.5
Metropolitan	39.9
City	36.5
Central Neurological	140.6

Mt. Sinai	37.5
Presbyterian	20.7
St. Luke's	31
New York	20.2
Montefiore	253.8

Cost of Care

Accepting the estimate of cost of each day of hospital care of all medical and surgical patients as given by each hospital (rates in 1920) Mount Sinai, \$5.40; New York, \$4.90; St. Luke's, \$4.66; Kings County, \$2.87; and Montefiore, \$2.59. Rates based upon 1921 data were as follows: Presbyterian, \$6.03; Bellevue, \$3.39; Metropolitan, \$3.10; City Hospital, \$2.68; and Central Neurological, \$1.60. The total cost to these hospitals of the bed care of the 4,522 heart patients admitted for the period covered was \$607,280.88. The average cost of each heart patient's stay varied from \$68.81 at Bellevue, where the length of permitted stay is necessarily brief, to \$657.34 at Montefiore, and \$149.00 at the Central Neurological, where the period of care commonly extends over many months.

The institutions of various kinds in and near New York City which accept patients convalescent from acute cardiac disease or from some form of breakdown caused primarily by disease of the heart, number eleven. With the exception of St. John's Guild, which is open three months, they are open throughout the year and provide accommodation for 312 patients (Table IV).

The beds assigned to convalescent heart patients vary from two at the James A. Moore Memorial Home, to eighty at the Burke Foundation. The total beds calculated on twelve months service in these institutions for all kinds of convalescent patients amount to 910. Thus the percent of convalescent beds in these particular homes, available for heart patients, is 34.2 per cent.

It is estimated that there are avail-

The heart patients have available only 312 beds or 13.8 per cent of all convalescent facilities.

Patients Accepted

All homes do not accept patients in all stages of heart disease even though the patients may be as a matter of fact convalescent from a more severe grade of disability.

The clinical basis for admission of patients to the various convalescent

1. Clinical classification of patients accepted is as follows:

Class I.—Patients with organic heart disease who are able to carry on their habitual physical activity.

Class II.—Patients with organic heart disease who are able to carry on diminished physical activity: (a) Slightly decreased; (b) Greatly decreased.

Class III.—Patients with organic heart disease who are unable to carry on any physical activity.

Class IV.—Patients with possible heart disease. Patients who have abnormal physical signs in the heart, but in whom the general picture, or the character of the physical signs indicate that they do not originate from cardiac disease.

Class V.—Patients with potential heart disease. Patients who do not have any suggestion of cardiac disease, but who are suffering from an infectious condition which may be accompanied by such disease, e. g., rheumatic fever, tonsillitis, chorea, syphilis, etc.

homes varies somewhat, but the classification of heart patients established by the New York Association of Cardiac Clinics¹ is used very generally, according to which the patients usually acceptable are those falling into Class I, II, IV, and V.

Admission to the Mineola Home is made through the central office of the Association for the Prevention and Relief of Heart Disease. It is hoped in the near future that a central office will serve as a clearing house where admissions to all convalescent homes taking cardiacs can be given and where the institutions may accept the classification and opinion, as to need of convalescent care, that is given in each case by a physician in attendance at one of the various heart clinics. Of the 312 beds available, 134 are for boys² and girls, the majority being for girls; 62 are for boys only; 76 for girls only; and 40 are for men and women. Five of the homes accept colored patients occasionally.

Duration of Stay

The duration of stay is not specified except in one institution, where a limit of three weeks is usually observed. In general the patients are kept as long as the character of care provided appears to be benefiting them. The average duration of stay

2. Excepting the thirty-six beds at Mineola and the six beds at Reed Farm for boys up to sixteen years of age, the provision of beds for boys is limited to those under the age of ten.

of patients in 1921 varied from twenty-one days to eight months. Omitting the maximum of eight months the average stay was about forty days.

The total days of care provided for cardiac convalescents in these homes in 1921 was 89,754. This represents 28.6 per cent of days care given all patients in these institutions, and 14.9 per cent of the days of convalescent care given in all the institutions for convalescent care in and near New York City.

Cost of Convalescent Care

The cost of each day's care of patients in these convalescent homes in 1921 varied from \$1.27 to two dollars. The total cost of care of heart patients in these homes in 1921 amounted to \$156,591.64, and the average cost for each patient's stay in a convalescent home was the sum of \$100.93.

Special Heart Clinics

Since the number of clinic sessions held each week, of hours of each session, and of physicians in attendance, vary widely, the most convenient and accurate way to report upon dispensary services as to give the number of physician-clinic-hours per week provided in any special field. This figure can then be used as a just basis of comparison of services among various communities, as a ratio of physician-hours of such clinic service per 100,000 of the population.

TABLE IV.—CONVALESCENT HOMES. CAPACITIES, LENGTH OF PATIENTS' STAY, COST OF SERVICES.

*Exact cost equivalent - cost estimated at \$1.60

There are now operating in New York City 43 special dispensary heart classes for children or adults, or for both, holding 56 sessions each week, at 24 hospitals or other clinical institutions. (Table V.) There are one hundred and ten physicians in attendance at these sessions giving a total of 301 hours of heart clinic service a week for each 100,000 of the population. The expressed opinion of those working in this field in New York City is that the clinic facilities and the attendance of doctors and nurses devoted to the supervision of ambulatory heart patients should be doubled if the obvious need for this service is to be fully met.

Cost of Service

There are the equivalent of 23 4/15 nurses or paid social service workers in attendance at these clinics, maintaining more or less home and personal contact with the patients, and serving whole time in that special field. From month to month during 1922, an average of 5,900 active patients have attended these clinics, and a total of 35,166 individual patient visits were made to these special heart clinics in the year 1922.

It is estimated that it costs fifteen dollars a year to provide reasonably adequate dispensary and social service follow-up care and supervision of an ambulatory heart patient throughout a year, if the medical services are provided free. On the basis of the 5,900 patients constantly in active attendance at the clinics the estimated cost of this service for heart patients if it had been complete in every respect would have been not less than \$88,500. Considering that the cost of dispensary care of heart patients was approximately the same as that of other patients attending the medical and surgical dispensaries³ in New York (\$0.67), and that in 1922 there were made 35,166 visits to the special heart clinics, we arrived at a cost of \$23,561.22 for this

dispensary service for heart patients in the year 1922.

In all probability the estimate of fifteen dollars a year per heart patient represents more nearly the true cost of care where the home follow up and social service is adequate than does a cost for heart patient care based upon the cost per patient visit for the general run of dispensary patients.

Estimated Cost of Care

The total annual cost of present hospital, convalescent home and dispensary care of patients with heart disease in the institutions studied is approximately: \$607,280.88, for hospital bed care, \$159,704.64 for convalescent home care, and \$23,561.22 for dispensary care at special heart classes. This estimate, which obviously fails to express the entire cost of this group of disabilities, deals only with that relatively small number of heart patients who reach hospitals and dispensaries. There is no sufficient basis of record to estimate the number and probable cost of care of heart patients in their own homes attended

schools, industry, the army, and in life insurance examinations (1) that approximately 2 per cent of people of both sexes and all ages are afflicted with heart disease of sufficient severity to require medical supervision; (2) that not less than 4.58 per cent of all admissions to general hospitals are suffering from heart disease of a seriously disabling degree; (3) that at least 9.35 per cent of all days of bed care provided in general hospitals are required for these serious cases of heart disease; (4) that not less than 5 hours of physician-clinic service per week per 100,000 of population, and probably at least ten such hours of service are needed to provide for care of ambulatory patients; (5) that at least one nurse or social service worker on full time is required for each. 100 patients attending special heart clinics and (6) that not less than 6, and probably at least twelve beds are needed for convalescent care of heart patients per 100,000 of population, and that the duration of such convalescent care will be at least 3 weeks in each case.

Since New York City has 31,618 general medical and surgical hospital beds, from which number we must deduct 3,134 beds used exclusively for eye, ear, nose and throat, skin, cancer and contagious diseases or 28,475 general medical and surgical hospital beds—and these are 75 per cent filled throughout the year—or there are available 21,356 beds, 365 days in the year, or 7,794,940 days. Of these 9.35 will be devoted to care of heart patients or 728,827 days. On the basis of the experience of ten large general hospitals with an average cost of \$3.67 per day per patient we find the probable total cost of hospital care of heart patients in New York City as \$2,711,236.44. There should be added the cost of at least twice as much convalescent home care (\$282,314.88) as is now available, and for lack of which there is unnecessary disability and early death. To this should be added the cost of special heart clinic services which do not at present more than half meet the needs—especially for follow-up of such patients—or \$297,300; and, further, the cost of services of bedside nursing of heart patients by the visiting nurse associations of the city. The service as rendered by the Henry Street Settlement and the Visiting Nurse Association of Brooklyn, amounted to \$5,169.40 in 1922. The whole cost so arrived at constitutes a total of \$3,290,000.72, which represents but the minimum basic cost of those sick from heart disease, and does not take

by private physicians.

It would appear from experience in

into account the losses in industry from the intermittent, part-time and what we may call half-hearted work which such handicapped persons can accomplish, or the cost of relief for persons or families which fall within the indigent or dependent group, where the often prolonged course of chronic disability from heart disease plays a large rôle, in the experience of relief agencies.

Recommendations

While this study was undertaken primarily in the interest of fact finding, the inadequacy of services available and the clear indications for specific improvements in facilities for prevention of heart disease, for the treatment and training of those already afflicted and not permanently disabled, and for suitable care of the totally disabled heart patient justify the presentation at this time of recommendations which concern numerous medical and social agencies.

(1) General hospitals, dispensaries and practitioners of medicine can contribute largely to the prevention of heart disease, by a quicker detection of heart lesions and lowered work capacity among the patients who pass under their inspection. Convalescent care to prevent decompensation as well as during periods of recovery is not sufficiently availed of. Brief periods—seven to ten days—of rest for apparently compensating heart patients serve a valuable preventive function and permit long postponement of the period of complete disability.

(2) Admissions to hospital from dispensary or private ambulatory office care should be arranged for at a much earlier stage of disability from heart disease than is the present practice.

(3) Most recent or acute cardiac patients should be kept at rest under hospital and convalescent home care for much longer periods than is the general practice at present. Prevention of serious scarring and deformity of valves, more effective adjustment to the obstruction or regurgitation by compensation through hypertrophy, and better assurance of permanent work tolerance, could be guaranteed if the period of rest and gradual restoration to full activity resembled more the practice followed in arresting active pulmonary tuberculosis than that commonly observed in medical hospital services for convalescents from many of the acute infections. The periods of acute hospital care are too brief for the needs of the patient, a

poor investment on the part of the hospital, and permit unnecessary subsequent preventable disease.

(4) The lesson so well learned by tuberculosis sanatoriums and dispensaries, that the case is not well handled until self-support in an occupation which spares the patient occupational hazards, has been selected and if necessary trained for, must be followed in the field of heart disease. Occupational training and vocational guidance for children and adults are essential supplements for prevention of chronic cardiac disability and valuable resources in developing compensation after adequate hospital rest and care.

(5) Although much has been done to meet the obvious needs of convalescent heart patients direct from hospitals, there is nothing approaching sufficient provision for the heart cripple, the permanently incapacitated dependent invalid who can in no way be restored to tolerable conditions of life outside of hospital care. There is needed urgently an institution of not less than one hundred beds devoted exclusively to the care of chronic heart cripples. By extension of existing insufficient services at the city institutions and at Montefiore Hospital and by readjustment of beds in our general hospitals, this seriously neglected class of patients could be further provided for. Hospitals which decline such patients because they wish rapid turnover of patients should be willing to set aside at least a few beds where prolonged care for heart patients is taken for granted, and no pressure for surgical cases or for epidemic emergencies of respiratory tract infections should be permitted to oust these helpless dependents. Extension services to the homes from existing heart clinics, comparable to the home care of the tuberculous, would meet the needs of some of this group of chronic heart cripples. Special service for a selected group of these patients in the homes might prove less expensive than hospital bed care and might well develop out of the existing heart clinics.

(6) It is not too much to hope that special jobs in many industries or even a special factory, shop, or trade unit, equipped to offer opportunities for continued occupation to the chronic heart cripple who is able to put in a part of each day in gainful work, may be provided to better the lot of this particular group.

(7) For the negroes of both sexes and all ages, the present wholly inadequate provision of convalescent

facilities which disproportionately handicap the 150,000 negroes of our population will in all probability have to be met by a more liberal policy and increase in bed capacity of existing institutions.

(8) Boys between the ages of ten and fifteen years, both white and colored, are discriminated against in the distribution of beds for heart convalescents. This lack can only be met to a trifling degree for the more robust and less recent graduates from hospital care by the opportunities at summer camps recently opened to what we may call "guaranteed cases," boy patients whom the physicians at the heart clinics approve for unrestricted exercise.

(9) With all the attention and endorsement given to the needs of the partially or wholly dependent heart convalescent, there is still an important need for a sanitarium or convalescent heart station for patients of means, akin to the admirable tuberculosis sanatorium developed for this very class.

(10) In the field of dispensary service the outstanding defect, namely a pitifully inadequate social service, can be met only by recognition of hospital and dispensary executives that their responsibility to heart patients is much greater outside than within the four walls of the examining room. According to the density of the population and the limitations to restricted districts of the sources of patients, one active well trained visiting social service worker or nurse can maintain the necessary follow-up of patients to the number of not more than 150 and usually of not more than one hundred.

The Association for the Prevention and Relief of Heart Disease intends to use its resources of education and persuasion to remedy as soon as may be the deficiencies of the services for heart patients here disclosed, and to follow this study with a careful analysis not only of the natural history of heart disease based on data already in process of collection, but to present a report upon the shortened working years of wage earners, due to cardiac disabilities, in a series of patients whose histories can be traced for a considerable period through co-operation among the social and medical services of this city.

First aid classes have been established for Federal employees at Washington in the Post Office, the Interior, the War Department, and in Navy and Justice Departments. Certain of the departments have two classes in first aid training.

Normal Training in Physical Education*

Based on Activities of the Chicago
Normal School of Physical Education

THE objective of the physical director is not the achievement of wholesome recreation for the population, nor merely the attainment in selected groups of hard musculature through planned and persistent muscular activity. It is not even the attainment of social control through directed play, though all of these ends are served and may normally be regarded as the logical by-product of a consistent program of physical education. His real purpose, however, is to find through the universal appeal of physical activity a means of education by which personality may be developed and effective, well coordinated response will automatically replace self-conscious, timid, ambiguous, and therefore, ineffectual effort in emergent situations.

Through physical education we are coming to know mind not for what it is, but by what it does. Mind is no longer detached, or considered detachable from the physical mechanism. The world of ideas is not the moral world, and the physical organization a base and despicable plane; but mind and body are one; personality is the complete expression of psychophysical being; in ways not mysterious even if only partially understood, effectual behavior finds organic registration, and the person who by chance or design manages to acquire through physical education immediacy of response along with breadth and variety of serviceable reactions is in a fair way to become the really superior person. Such a person almost surely stands out among his fellows and is everywhere conceded leadership by the unorganized throng.

Superiority then, in the presence of native ability, awaits full expression. This has particular weight in view of the train of pathologic woes that are entailed by halting or suppressed expression and the instability of persons who find themselves unable to translate mental and physical stimuli into immediate action. Errors and delays in response are to the physical educator explained in terms of psychology.

But the philosophy of physical education is not so much the subject of this discussion as the need for universal physical education, or rather, the

development of a sufficient number of adequately trained physical educators to make physical education an integral part of every curriculum in every school. It is in part to the lack of a trained personnel and the consequent fact that any sort of a self-styled director can instantly sell himself on the open market that the whole field of physical education is in confusion. Voluntary workers, entirely untrained and it may be unsuited to their task, have everywhere undertaken to organize play and recreation. Many of them have done remarkably good work and from the ranks of voluntary workers come some of the most promising recruits for consistent training in this field. The activities of Y. M. C. A. and Y. W. C. A. groups have progressed from unplanned, un-directed play opportunities to thorough programs under efficient guidance. Industrial organizations have launched competitive and social games that are a distinct and separate contribution. The orthopedists have developed highly specialized methods for corrective and developmental purposes, and rehabilitation services are a new departure with a purpose and a technic all their own.

The variety of purposes served by

these several groups would naturally seem to indicate specialties superimposed upon the general education required of physical educators, but it is not so. These special activities carry a specific appeal that is much stronger than any purely educational project and so got themselves established almost on a professional basis long before the need to supplant the old systems of mind forcing by the modern method of all round training was realized. Meanwhile, in their various ways the several groups had made good progress. Physicians were indexing physical vigor on the basis of lung capacity; workmen's compensation was awarded on estimates of restored function; the output of the factory was found to fluctuate in perfect accordance with the unnecessary motions of the operatives; and ratings of dependability—conceded to be mind plus physical training—were made on the basis of responses under stress and strain.

Naturally, the deductions that came from the observation of such cause and effect relationships have led to cults, and fads, and unjustifiable generalizations. Certain procedures have been exploited as cure-alls, rhythmic sequence has been made to account

The library at Greenwood Dormitory stimulates scholastic activity on the part of physical educational workers at the Chicago Normal School of Physical Education.

Student room at Greenwood Dormitory.

for logic and the lack of it for fundamental physical defect; on individual initiative or collective propaganda exercises more or less questionable in value have been energetically practised. The remedy is plainly in the direction of more and better leaders and these are secured only through accredited students from reliable training centers.

The work of the Chicago Normal School of Physical Education is illuminative. Organized to meet the growing demand made of normal schools for supervisors, directors, and teachers in the important work of physical education, selected individuals who by taste, previous training, and personality seemed capable through further special training of becoming community leaders, are offered courses not in physical development merely, but training in such fundamental sciences as anatomy, physiology, biology, psychology, and pedagogy. Music, literature, public speaking, voice improvement, and the history of education contribute their cultural value. The faculty of the school consists of men and women of wide reputation in education for their ability to bring the students under their direction to the highest possible personal development. It is understood that pupils who are found after one year of training to be unadapted to the imposed standards of all round development are not permitted to continue the course.

Two departments of instruction are maintained. The normal department affords practical and theoretical in-

struction to students who desire to become directors of physical education, playground supervisors, dancing teachers, or swimming instructors. A nice balance between the physical and mental program is maintained. The course is not based upon any "system" of physical training. Basic cultural courses take care of interpretations, and the application of scientific principles of each branch of the profession is assured. The product of the school is a type of strong teachers,

adaptable to direct community programs as well as to undertake body building as a fundamental part of the school curriculum. Moreover, they are missionaries to a people who are everywhere lacking the full and efficient life which ensues upon a regime of balanced play and work.

There is also available a six weeks course on camp training. Personal hygiene courses treat of clothing, diet, bathing, and the care of the hair, skin and teeth. General hygiene includes the study of infection and the ethics of social responsibility in the matter of public health. Lectures and practice in physical examinations enables the students to exclude any applicants for training who show prominent signs of physical disorder. The first aid course provides against cases of emergency and accident. Summer normal courses provide facilities for advance instruction for progressive work in this field.

The criticism recently made before a meeting of physical education teachers that the rank and file of workers in this field have not yet achieved professional status has no weight among groups who submit themselves to the disciplinary regimen maintained here, and advocacy of the physical betterment of our whole people cannot find better support than that afforded by consistent, trained, and universal leadership evolved through rigid educational methods among physical educators.

The gymnasium class in action. Group as well as individual methods are employed. The new fireproof school building affords every essential of appointment and apparatus for gymnastic work.

Yale Establishes Undergraduate School of Nursing

PRESIDENT James R. Angell announced recently the establishment at Yale of the first university undergraduate school of nursing in the United States, the funds for which are to be provided by the Rockefeller Foundation. Fifty thousand public health nurses are needed in the United States. Only eleven thousand are properly trained to meet the demand. The case is now especially urgent. Therefore emphasis will be placed on public health nursing in the basic course at Yale.

This school is a new departure in education, first because of its organization and second because of its curriculum. It will be the first school of nursing organized as a separate school in a university, with its own dean, its own faculty, buildings, and budget. Heretofore nursing schools have been dependent upon medical schools and hospitals. In its curriculum the Yale school will break away from the present apprenticeship system of nurse training. That system, subject as it is to the labor demands and exigencies of hospital needs, and now abandoned in other professional fields, no longer provides satisfactory preparation for the nursing profession. It absorbs the time of the student, endangers her health, and leaves too little opportunity for educational activities. In the Yale school the nursing course will focus attention upon the educational, training of the student, eliminating many routine tasks which contribute little or nothing to this training.

By adopting this educational plan, the period of preparation for nursing can be shortened. Just how much time can be saved in the basic course under such an educational plan as contemplated, in distinction from the present apprenticeship method, has never been determined, and one of the first tasks of this new school will be a study of the period and arrangement of time required to prepare a young woman for the responsibilities of nursing and for the opportunities which are open to her profession. Recent studies indicate that a period of about twenty-eight months will be required for the course.

The requirement for admission to the Yale University School of Nursing will be a high school course or its equivalent. Primarily for the girl without college training, provision will be made for an elective pre-nursing period of university work, chiefly in

the sciences. The schedule will be somewhat elastic in order to permit young women of different preliminary training to develop in keeping with their individual aptitudes and ability.

Throughout the course an attempt will be made to present all the factors which contribute toward the diagnosis, care, and treatment of disease, and which have relationship to the conservation of health. Patients will not be considered as hospital "cases" only, but such factors as heredity, environment, child development, psychology, economics, sociology, industry, and public health will be presented in

which will ultimately be developed as a part of the Yale program. Whether or not the graduate of this school intends to go into administrative nursing, nursing education, school or industrial nursing, into the nursing of contagious diseases, tuberculosis, or mental diseases, she will have had a well-rounded preparation and understanding of the community as well as the bedside aspects of nursing and some understanding of the factors which contribute to sickness, the control of which makes the prevention of disease possible.

The plan includes a coordination of the educational work of the New Haven Visiting Nurse Association, one of the best community nursing organizations in the country, and of the Connecticut Training School for Nurses in the New Haven Hospital.

The Rockefeller Foundation after a survey of the United States has decided upon the support of nursing education at Yale. New Haven is a community of the best size for health activities. It is a university center. The Yale Medical School is well-organized, with the public health conception and a full-time staff. The New Haven Hospital has all services effectively represented. In New Haven visiting nursing is well under way at present, adequately supported and properly organized. All these conditions make possible here the development of a new and distinctive contribution to education, medicine, and the public welfare.

Miss Annie W. Goodrich, director of the Henry Street Visiting Nurse Service and assistant professor of nursing at Teachers College, Columbia, has been appointed dean of the new School of Nursing. Commenting on the appointment President Angell said: "It would have been impossible to find anyone more competent to undertake the difficult work of organizing the new institution. Miss Goodrich's extraordinary breadth of experience, her sanity of outlook, and her administrative capacities will be of the greatest value to the University in this new and interesting enterprise."

Although recognizing the project as an experiment, that its success seems assured under the leadership of Miss Goodrich is the opinion of experts in public health, nursing, and hospital work, who expressed great satisfaction over the appointment. Dr.

Miss Annie W. Goodrich has been appointed dean of the new school of nursing at Yale University. She has been assistant professor of nursing at Teachers College, Columbia University, and director of Nurses at the Henry Street Settlement. She served for a period of years as superintendent of nurses at the New York Post Graduate Hospital.

their bearing upon each problem as it is studied. Such a plan will emphasize sickness in its true relationship as a family, community, and public health problem, and properly to develop such a conception the new school will embrace field work and community nursing as a part of the basic training. This attitude will be emphasized throughout the entire period and a considerable portion of the course will be devoted to these features.

The general plan of the school of nursing should provide in this basic course a well-rounded preparation which will permit graduates to enter directly into community, hospital, or private duty nursing, or to proceed into one of the various special branches of nursing, opportunities for

C.-E. A. Winslow, professor of public health in the Yale Medical School and chairman of the Committee on Nursing Education appointed by the Rockefeller Foundation, referred to her appointment as peculiarly appropriate since "she was a member of the Committee on Nursing Education which after an extensive study of this subject for three years laid down a plan by which the training of the nurse can be organized on truly educational lines and had a large share in framing its recommendations. Experienced, energetic, and scholarly, there could be no one better fitted to place the profession of nursing in that high place in the academic world which it has earned by its brilliant service to mankind."

Dr. Willard C. Rappleye, superin-

tendent of the New Haven Hospital and professor of hospital administration at Yale says that "the contribution which the new school can make to the nursing education of this country depends primarily upon its leadership. Yale is indeed fortunate to have secured the services of one of the greatest living nurses, and under her guidance it is hopefully anticipated that the Yale school may make a great contribution to the field of nursing and public health."

Miss Goodrich's varied service both in hospital and teaching work is as follows: Superintendent of nurses, New York Post Graduate Hospital, 1893-1900; St. Luke's Hospital, New York, 1900-02; New York Hospital, 1902-07; Bellevue and Allied Hospitals, 1907-10; inspector Nurse Train-

ing Schools, New York State Education Department, 1910-14; lecturer, Teachers College, Columbia, 1904-13; assistant professor of nursing, Teachers College, 1914; director of nurses, Henry Street Settlement, 1917; dean of the Army School of Nursing, 1918-19. In 1921 Mount Holyoke College conferred upon her the honorary degree of Doctor of Science and the War Department recently awarded her the Distinguished Service Medal. Edwin R. Embree, secretary of the Rockefeller Foundation, says that "she is unquestionably the outstanding figure in nursing education in America today. She has made a distinguished success equally as director of the great visiting nurse service in New York City and as teacher and dean."

Fiftieth Anniversary of Social Workers

THE National Conference of Social Work convened in Washington, D. C. May 16-24 to celebrate its fiftieth anniversary. The presence of guests from a number of foreign countries gave to the meeting an international aspect which up to this time had not been evident, also the participation of government officials and governors from various states marked its acceptance as a great interpreter of current social thought and movements. More than four thousand delegates registered their attendance, which exceeds all previous attendance records, while more than thirty organizations, committees, and groups of allied interests held meetings coincident or in connection with the general conference.

President Folks and Secretary Hughes in their opening addresses sounded a very distinct note of optimism which pervaded the meetings, the necessity for the prevention rather than "the cure of sickness and poverty, and the reform of criminals which has been found to be, as a rule, uncertain, incomplete, temporary, expensive and long." "We are only on the threshold of a preventive program. We have devised and sharpened our tools; we have worked out our methods. It is now time to develop our fragmentary program into one that is more comprehensive and definite. Mr. Hughes remarked that the United States has scrapped world distrust and that we now have "every assurance of abiding peace, so far as our relations with other peoples are concerned." The position of the social

worker as one familiar with the problems of adjustment is peculiarly fitting. "It is in the quiet humane work done in the manifold fields of social activities that the world finds the surest promise of peace, and it is the only road that will lead humanity to its desired goal. It is the thought and intent of the heart that count. The roots of amity and mutual confidence must be struck deep in the thoughts and convictions of people until war is unthinkable."

Each day of the conference was given over to a discussion of the general problems of Health, Industry, Law, and Government, the Church, the Home, the School and Public Opinion. It would be impossible to review the papers given in the space and time allotted. Dr. Robert M. Yerkes of the National Research Council in his discussion of intelligence tests pointed out that the scientific study of human life, the gradation and evolution of traits and characteristics is of recent development but nevertheless the measurement of mentality advances steadily and systematically accumulating a wealth of experience invaluable and increasingly serviceable to mankind. Dr. W. F. Lorenz, professor of psychiatry, University of Wisconsin, discussed the results of a recent survey. He pointed out that "the mentally abnormal and feeble-minded within the prison should be segregated and breach of prison discipline by irresponsible should not be punished in the same manner that may be necessary for the mentally responsible. Proper vocational training in penal institutions is necessary

in order to rehabilitate the man." Dr. Frankwood Williams discussed the impasse which comes in the interpretations of evident facts due to the mental attitude, conscious or unconscious. The facts which indicate a given situation are a common knowledge but we must give more time, attention, and effort to the ineffective solution, to the significance and reason for opposition and delay. It is the function of the social worker to study normal life just as it is the intent of the psychiatrist, and not, as Mr. Mallon pointed out later, to conceal the faults of industry or society "playing the part of the undertaker who spirits away our failures."

Dr. Ludwig Rochman, director of the Health Section of the League of Nations, told of the work of the bureau in coordinating the reporting of communicable diseases and the spread of information concerning administration methods and expedients. The problem of stemming epidemic diseases in Russia and the border states was a peculiarly difficult one. Between three and four million persons have died of typhus alone in Russia since 1918. Nine million cases of malaria have occurred, in some localities the disease was of a very virulent type in which forty out of a hundred cases died. Dr. Biggs discussed the development of health and preventive measures in New York State, pointing out the lengthened span of life and the possibility of further enormous saving of life. Dr. Farrand of Cornell, spoke of the history and development of disease prevention, health promotion, and the increased importance of

health in social and economic programs.

The chief factors in promoting the health and efficiency of industrial workers are the payment of adequate wages, continuity of employment or participation in the soundest plan of unemployment insurance including safeguards from excessive risk from injury or disease as shown by Dr. Wade Wright in his discussion of the "Minimum Standards for Health in Industry." Only a small percentage of workers are employed in plants maintaining health departments.

The problems surrounding the defining and meeting the health needs of the Southern negro are inextricably interwoven with the health of the whites. Mr. T. J. Woofter, Jr., of the committee on interracial cooperation, Atlanta, Ga., showed that the masses of negroes, especially rural negroes, are ignorant of the requirements of sanitation, under disadvantage as to living conditions, unable to change these conditions, and woefully lacking in the organization through which a health message could be brought. Their death rate from tuberculosis is twice that of the whites, and their infant mortality too high. Dr. Rankin of North Carolina, stated that the needs of infancy for medical services are not one-fifth supplied under present conditions. "The age of childhood with from 10 per cent to 20 per cent of its population malnourished, 20 per cent with defects of vision, 5 per cent with adenoids and tonsils, 75 per cent in need of dental treatment and the entire group made more susceptible and less resistant on account of these conditions that impair vitality, needs not less than five times the medical services which this age group now receives."

Personnel problems in the store and in the factory have much in common. A common attitude has been that the interests of employer and employee are fundamentally opposite but the modern personnel manager has for his greatest task the production of harmony. Miss Oldenerentz stated that the review of discharges by the personnel worker is one of the most important steps in the work in reducing and defining labor turnover, "a serious disease of industry." The discussion of industrial technic and social ethics by E. C. Lindeman indicated the confusion and disturbance of our advance in industry not material, but social and actual.

The abolition of poverty and the creation of a public service of such practical opportunity and unques-

tioned ideals that it may be regarded as a desirable career and activity may be accomplished in the near future. Mr. Kelso sees the foremost child-care agencies as child-placing institutions. "Standards of home life, standards of efficiency in the supervision of children placed in foster homes have come into being. The congregate institution is to disappear, leaving behind it the temporary shelter and keeping these only for the briefest practicable period."

Mr. Hoover was introduced to the audience as "the greatest social worker of all times." The organization of American relief work in Europe, the defeat of the famine in Russia and elsewhere were truly remarkable. Even in Russia with American aid two million lives were lost, but without it twenty million would have been lost. Even after relief was unnecessary for adults the special problems of feeding and malnutrition among children necessitated the continuance of the work there which it is planned now to abandon with the harvest of 1923. The experience and organization of the American Relief Administration have been merged with the American Child Health Association and through them will be utilized for the benefit of American children. The good will and affection this work engendered is worth more he added "than all the battleships that could be floated in the Atlantic Ocean."

Mr. James J. Mallon of Toynbee Hall discussed the rise and development of British labor ideas and the desirability of a fuller exchange of ideas between forces in England and America. It is the function of industry not to fill the pockets of employers and financiers, but to minister to the high purposes of life. "If industry is in the future to hurt and throw down; if it is to remember the humanity of the worker, respect his personality, safeguard his strength, develop his intelligence, enlarge his status and dignity, its nature must be transmuted. It must aim not at making a profit, but at saving mankind." Or, as Mr. Johnson said, a little later "insufficient wages, insufficient leisure, insufficient employment, fatigue and unwholesome or improper working conditions give rise to a great part of our social troubles."

Dean Pound in his discussion of "Preventive Justice" pointed out the necessity of meeting a problem before the same is actually acute. "We need to reach things very much further back." "The team play between law and social work is necessary, and if

applied rightly, preventive justice is not far in the future."

Mr. Porter R. Lee in his discussion of "Changes in Social Thought and Standards which Affect the Family" gave one of the most original, fearless and thoughtful contributions to the conference.

The school as an increasingly important social factor, as a means of interpreting experience and social ideas to the child cannot be under-estimated. The same thing is true of the child of school and pre-school age. The school in reality fulfills a double function. "It furnishes young children from average homes a better opportunity for physical, mental and social development than the unaided home, and it furnishes unparalleled opportunity for the instruction of young women in the things every parent should know." According to Mrs. Woolley the environment and activities of the child outside of the school frequently defeat the advance made within the institution, for which reason a careful analysis and understanding of the child and his family is particularly desirable. "The public school has been the greatest single force in breaking down class barriers, those between rich and poor and those occasioned by difference of creed, language and race." It has done this, Dr. Dewey continues, by the sheer force of being a public institution which has assembled children and youth as a common ground for common work and play. We have reached a point when the social work in the public schools must be performed more consciously and constructively. The nation has reached the limit of its stage of unconscious movement and expansion, it has reached the stage of economic and social problems.

We can not trust any longer to natural, unguided working of democratic forces. We have to take stock, plan ahead, reform evils, and make achievement secure. The educational system must be the chief instrument in this movement—the greatest need is the awakening of teachers to their social office and function and the responsibilities therein entailed. They must recognize that they themselves are, first of all, social workers, constructive engineers of future society and its statesmen in the deepest sense."

What the public thinks about social work is a theme not to be disregarded, 75 per cent nuts as one puts it. The news value of social service work and activities, and the amount of space allotted editorially and in news columns were particularly interesting.

Physical Training at South Bend Hospital

EARLY mental training has been a foremost principle of practice in our civilization for many centuries, as it has been in every civilized nation. The careful, intricate, and well developed plans for mental training that obtain everywhere in our land are not exceeded by those of any other social or commercial development. All agree that this is as it should be. No one would detract one iota from the importance of this procedure, but physical training, no less important, is still in its infancy.

Dr. W. H. Baker, who directs the physical educational work conducted by the social service department of the Children's Dispensary and Hospital, South Bend, Ind., has discussed this subject in a recent communication as follows:

A child before the age of six, by its mother's knee, receives its first rudimentary mental gymnastics, if we may speak of the early mental training in that way. When it enters school at six years, a suitable building and skilled person takes it into charge and carefully and thoughtfully carries its mental training through until it finishes the public schools and perhaps our universities.

The physical training at the ages from six to twenty years is, in most instances, sadly neglected. There are no well trained teachers in physical development that make a careful study of the child's physical needs and administer accordingly, as he goes through the many grades up to twenty years of age, when he should be able to continue the work fairly well undisturbed.

I would not under-rate the excellent

*Paper delivered before the International Committee for the Elimination of Unnecessary Fatigue of the Society of Industrial Engineers.

work that is being done each day by our nurses, teachers, and other public health workers in the detection and prevention of disease; but there are many who have defective bodies and practically no disease, whose homes have fair ventilation, good food, and whose bodies have fair care in general, yet who have not enough physical exercise of the right kind to keep the body in good condition. This we see in every group of boys in our Y. M. C. A. or of girls in our Y. W. C. A., when they have their trunks on, ready for a plunge into the tank. Their bodies are not well formed; the muscles are flabby instead of strong; the skin looks as if it had no blood in it; they are poorly developed; muscles and ligaments are weak, causing flat feet, curved spines, protruding abdomens, sunken chests, rounded shoulders, dangling arms, loose joints, and other equally bad fatigue signs and symptoms.

It is not an uncommon occurrence to find these children with some form of disease. These are sooner or later detected by the school nurse or physician and quite effectively treated. On the other hand, there are more and other children having no form of disease, but who from heritage or from the lack of proper every day exercise, are physically unfit.

Muscles and other tissues of the body will not get strong if they do not function. Neither do the mental facilities. It is therefore quite as important to give physical training intelligently applied, as it is to train the mind. And physical education should go hand in hand with the development and mental training of the child.

Those children who are physically weak should have special care if needed, and put into physical classes or groups of similar character for physical betterment. In order to do this, it would take one trained in such work and one who could give special and individual attention to each child

according to its special needs. This would require not only gymnasiums, but small posture rooms properly equipped, in order to give personal attention to those who need it. A weak muscle in the back that causes round shoulders or a lateral curve to the spine could better be demonstrated and better and more intelligent cooperation obtained if this child could be put before mirrors beside a child with a normal spine, and a demonstration of the curvature and the method of training be shown from day to day until results are obtained. Later such a child could be placed in groups with those of similar disorders. It is wholly unnecessary to picture what sort of a citizen a child with a strong physique will make compared with what he would have made had his physical condition been defective.

Fewer physically weak and otherwise defective conditions would exist if children were initiated early with the same intensity and determination for development of the physical being as we do the mental development, and there would be very much less suffering from illness later on in life, due to lack of strong bodies. It would especially benefit the girls of our country who later have to undergo the rigors of motherhood, and who too often, are physically unfit for such an ordeal.

The social service department of the Children's Dispensary and Hospital Association under the direction of Gertrude W. Smith, was organized in February, 1922. It is administered by one paid worker and volunteers. Stenographic work is done by volunteers. One form of record is used, no record being made of short service cases.

Acceptance of cases is based on medical diagnosis. All orthopedic, tuberculosis, mental deficiency, congenital syphilis, chorea, cardiac cases

All these children, patients of the orthopedic clinic of the Children's Hospital and Dispensary Association, South Bend, Ind., are receiving the benefit of persistent and definitely planned muscle training to overcome their defective posture.

Prescribed exercise, constant supervision by workers trained in the special methods required, and individual attention are pre-requisites for successful therapeutic exercise. The posture rooms of the dispensary are fully equipped for the work.

Shoes for Summer Comfort

FRESH, upland breezes; a dip in the surf; cool, summery costumes; light, comfortable Cantilever Shoes—these are some of the things that make warm weather pleasant.

When Summer days test the feet you will find welcome relief in Cantilevers. In them your feet enjoy freedom and agreeable support. Whereas, shoes with stiff soles, rigid shanks, high heels and tight toes distract your mind and make recreation difficult.

When your foot is hindered in its proper functions, and becomes swollen from restricted circulation, the sensation of discomfort is Nature's expression of disapproval. But comfort and ease are all that you feel in the Cantilever Shoe. Largely because the flexible shank fits the flexible arch of your foot, supporting it with friendly aid but leaving it at liberty to exercise and grow strong.

Ample toe room, a natural sole line, and a low, medium or

Cuban heel contribute to your comfort in the Cantilever Shoe. The materials are lightweight and soft. The lines are in keeping with this season's style trend and present an attractive appearance.

Women everywhere are enjoying the freedom and comfort of Cantilever Shoes. Thousands have learned that the secret of arriving fresh and attractive at the end of a journey — is to wear Cantilevers when traveling. And to supply the widening circle of Cantilever friends there is a store in nearly every city in the country.

Except in New York and Chicago, there is only one store to each city.

If you do not find the name of a Cantilever store near you in the partial list at the left, write the manufacturers, Morse & Burt Co., 15 Carlton Avenue, Brooklyn, N. Y. When they send you the name and address of a store near you which sells Cantilever Shoes, they will also enclose their new booklet which tells about feet and shoes in an interesting way.

Authorities, Physicians, Osteo-
paths, Directors of Physical Edu-
cation, Editors, Stage Celebrities
and prominent women everywhere

Cantilever Shoe

are referred by the physician. All unmarried mothers from the pre-natal clinic are taken for intensive work. Dental clinics as well as eye, ear, nose and throat, pediatric, prenatal and orthopedic clinics are conducted regularly.

All children under sixteen are treated. There is no fee. Applicants are investigated by a worker from the Associated Charities staff, who hands her report in to the superintendent with no recommendations. The Social worker has the privilege of recommending a patient for care.

Most of the children are Hungarian and Polish. Improper diet is the hardest problem to deal with in the home. There are many cases of poor posture. These children are often discovered by the pediatrician when the child comes for some other trouble. He is referred to the orthopedic department and the orthopedist then refers the patient to the physical education department of the Y. W. C. A. or Y. M. C. A. with definite instructions for exercise. The physical director of each organization attends the orthopedic clinics. This is made possible by the close cooperation of these organizations.

The children are sent three times a week to posture class. Each case must be followed by the social worker as it is difficult to make the parents realize the necessity for this class when the child is not ill. It is impossible to do intensive case work on all of these posture cases. An average of seventy-five cases a month is carried. The most intensive case work is done with the unmarried mothers from the pre-natal clinic with some orthopedic and all cardiac cases.

Because of the lack of facilities for hospital care for cardiac or choreic cases, the patient must be cared for at home. Absolute bed rest for a boy of ten years is hard to secure in the home, where he does not think he is ill and his parents cannot understand. Here the food problem is most discouraging and these cases require constant visiting and admonitions from the worker.

The pre-natal cases are taken as referred by the doctor or superintendent. Hospital arrangements are made and both baby and mother followed afterwards. The social worker sends patients in to the dental clinics but only those cases referred to the orthodontist are carried by the worker. Braces required for the orthopedic clinic are provided through a fund given for this purpose by an individual, but in cases where the family is able to pay any part of this amount,

After individual work has assured progressive improvement, these little patients are arranged in suitable groups and given the added incentive of the fun involved in co-operative effort.

they do so, the social worker being responsible for this. Glasses for the children are supplied through the school nurses for public school children, the dispensary furnishing those to parochial school or preschool age children when absolutely necessary. All cases of suspected tuberculosis are referred to the tuberculosis clinic. Social need as observed by the superintendent upon admission of the patient to a clinic is referred to another agency if there is no especial medical situation.

Because of the foreign element, further schooling is hard to obtain and the children have almost no recreation. The social worker is able to accomplish this sometimes because of her contact with the family, but it takes time. Explaining to the parent so that he thoroughly understands what the worker is trying to do, teaching hygiene and proper feeding in the home and interpreting the dispensary to the community, are the chief problems of the social worker. If a patient moves from the city, a summary of his record is sent to an agency in the community where he is going, if he still needs further care.

The greatest amount of the social worker's time has been spent on cardiac patients referred feeding cases, and orthopedic work. During the past 11 months, 1,580 home visits have been made by the Social Service Department and 886 calls. Many calls were made on cases not carried as social service cases.

The Shreveport narcotic clinic, known as the Public Health Hospital, has been closed. It was the last of its kind in the United States.

Village Cooperation for Medical Services

Some years ago a young physician, Dr. E. S. Haworth settled in Sharon, Kansas, but his practice was so limited that he was forced to move away. For the next three years Sharon with its 325 inhabitants, eleven miles from the nearest town, was for the greater part of the time without a resident physician. Accordingly they urged Dr. Haworth to come back. He called a meeting of the business men of the village and laid before them a plan which was accepted without a dissenting vote.

The essentials of this plan are as follows: The Sharon Health Association was formed with a membership composed of both, families and individuals. When the head of a family becomes a member the entire dependent household receives the benefits of the organization. The physician is furnished with an office, telephone, light, and fuel, and paid an annual salary of \$3,000, which is raised by assessing each member an equal amount—that is, in case of a membership of 300 the annual dues are \$10. No annual assessment shall exceed \$15, to be paid in two equal installments in advance, after which the members receive without additional charge the services of the physician, except in major cases such as require hospital attention, these costing extra in proportion to the services required. For each childbirth or abortion an additional fee of \$10 is paid to the association for the creation of a maintenance fund. The members pay for drugs and surgical dressing individually.

Many other interesting details of this scheme was given by F. B. Ross in *The Survey*, April 15, 1923.

Telephone Company Continues Benefit Fund

The plan for employees' pensions, disability benefits and death benefits has continued in effect throughout the Bell System during the past year, thus completing a decade of existence.

The average pension bestowed by the company is \$51. There are at present almost six hundred employees on the pension rolls. The number of cases of sickness which occurred during 1922 among employees eligible to benefits under the plan was 32,185; the aggregate benefits \$2,853,627. The total accident compensation was \$828,318.

The total amount of payments during 1922 was \$4,371,208.

Hallux Valgus and Bunions What is Your Method of Treatment?

The usual form of treatment is palliative only. To furnish your patient not only temporary but lasting relief it is necessary to remove the cause. This is successfully accomplished by mechanical correction. The subluxation at the metatarso-phalangeal articulation must be restored. Where there is a weak arch involvement this also should be treated.

You can win the everlasting gratitude of foot sufferers by advising them the successful way to secure comfort through the use of

Dr Scholl's *Corrective Foot Appliances*

These thoroughly modern and scientifically designed appliances form the basis of mechanical treatment for foot malformations as practised by leading orthopedists throughout the world. They are sold and fitted by leading

shoe dealers and surgical instrument houses everywhere.

Write for new pamphlet, "Foot Weakness and Correction for the Physician," just published, including chart showing exercises for flat-foot as endorsed by Medical Department, U. S. A.

The Scope and Cost of Health Examinations*

EARLY in the work of the Committee on Dispensary Development, it was apparent that any general plan for studying and improving dispensary service must include finding out at first hand what families living in crowded districts of New York could secure in the way of care during sickness, and preventive service in promoting health. It was necessary to know what phases of sickness and health work were not being met by the existing facilities in private practice, dispensaries, hospitals, and health centers. It was first thought that a good way to get this information was to work with a dispensary unattached to a hospital, using it as a base for study of health and sickness problems in a limited area. But it proved impracticable to reach a satisfactory working plan with such a dispensary. This threw at once into relief some of the main obstacles to health conservation work—namely, that few of the doctors serving in dispensaries have an active interest in preventive work; that boards of trustees and administrators of some dispensaries do not appreciate that medical treatment should go farther than giving out drugs; that the lack of follow-up for patients treated at dispensaries often leads to a false optimism that they are cured if they do not come back; that the technic of health and preventive work has nowhere been developed, and is almost as new to the personnel of most dispensaries as a new profession.

This situation made it apparent that there should be an experimental period during which the technic of health conservation could be developed within a professional group and through which the reaction upon individual patients and neighborhoods could be studied. As the health examination is a key to preventive work, the most appropriate step seemed to be the establishment of health examining stations where physicians, nurses, and social workers might ascertain what is the true condition of people presumed to be in good health because they are not complaining of ill health; to learn how health is conserved rather than mended, and to help to educate a small portion of the public in the same direction.

The real difficulty in conducting a health clinic lies in finding healthy persons to attend it. In this study the 872 supposedly healthy persons observed revealed on examination only twenty who were not in need of health direction. Practically all of the socially dependent group stand in need of medical treatment.

Impractical people who spell service in capital letters, without counting the cost, will find this report an illuminating document in medical economics.

Private agency, state subsidy, and all the available social machinery we have must serve and serve intelligently to meet the needs disclosed.

The stations were established in connection with various district social agencies, so that while developing the technic of health conservation, data could also be gathered on the health conditions of the social groups which the agencies served. The work is under much obligation to Dr. Haven Emerson, who acted during the year as medical consultant.

Health Clinic Submerged

Late in October, 1921, health examining stations were opened at the Mulberry Community House, 265 Mott Street, under the auspices of the Association for Improving the Condition of the Poor; at the Thirty-ninth Street Neighborhood Rooms, 315 East Thirty-ninth Street, maintained by the Community Church; and at the Seventy-ninth Street Branch of the Henry Street Nursing Service, 232 East Seventy-ninth Street. After six months of work in these stations, one afternoon and one evening session being held every week in each of the three, it was hard to find the health work under the avalanche of calls for examination of the ill. The purpose of the Committee—to do health and preventive work—was being subverted by the demand for advice as to sources of treatment for the sick. This demand was met, the information as to treatment resources being supplied, and moreover, after the examinees had been told where to go, they were followed along to see how they fared in getting the treatment they required. This follow-up has thrown light on the types of medical treatment which

can, or cannot be obtained satisfactorily under existing conditions in New York.

It became essential, then, to open another station where a group could be reached that had health needs, not primarily sickness needs. Greenwich House, a social settlement on the West Side, was selected because it is frequented by people whose prime object is not the relief of illness, but who avail themselves of opportunities for physical and mental improvement. The work with such persons has raised new and interesting problems of method.

At all the stations except one, examinees were required to pay a nominal fee in order that they would respect it the more. At the Mulberry Community House, where the Association for Improving the Condition of the Poor conducts an experiment in health education through visiting nurses, this fee was waived, as the Association has adopted the principle that health service should be as free as education.

The physicians and their assistants at the stations were all salaried. Otherwise, it was felt that physicians would not feel it obligatory to attend regularly and promptly, and would underestimate the value of the work as compared with medical relief. Almost the whole of a physician's training has impressed upon him the value of his work in dealing with disease and serious conditions. Almost none of it has been directed to show that preventive measures are as important as remedial. Considering any patient's life as a whole, it is surely as valuable to him to be kept from being sick, as to be helped when he has fallen ill of a preventable disease.

In this first stage of a new experiment it was essential to find how it should best be conducted, that is, method was important; and equally, the research that made it possible to decide upon the method. For example, it may not at first glance seem essential that a policy of free or paid service was a question requiring careful deliberation and extensive inquiry. Had it not been so regarded, the choice of the wrong policy in this one respect might easily have made the whole year's work of negative value. If free service had been the keynote of the health stations, and at the end of the year it had been found that being free it was regarded lightly, that the point of the value of a health ex-

*Report of a year's practical research under the direction of the Committee on Dispensary Development, New York, by Michael M. Davis, Jr., Ph.D., and Anna Mann Richardson, M.D. 1. This includes the 872 above mentioned and 98 additional examinations, i.e., 67 from the Greenwich House and 31 from Thirty-ninth Street after January 1, 1923.

In furunculosis and similar disturbances

*Careful tests demonstrate that
yeast produces a rise in the
leucocyte count . . .*

The value of yeast in curing furunculosis and similar conditions has been ascribed by numerous investigators to a hyperleucocytosis following its administration. Now a recent series of tests has confirmed their hypothesis in this regard.

Rabbits of the same age and weight were kept under precisely similar conditions. The tests were conducted under the strictest scientific control, to preclude the possibility of error.

After the administration of Fleischmann's Yeast, there was a definite rise in the leucocyte count which was roughly proportionate to the amount of yeast ingested.

To make sure that the additional protein ingested could not alone be held responsible for the leucocytosis, some of the animals were given live yeast and some were given yeast that had been killed by boiling. The live yeast

proved the more effective, showing that the leucocytosis was due to the action of the *living* cells.

Not only does yeast produce a leucocytosis, but its vitamin content is highly beneficial, and experiments have shown that it also assists regular intestinal activity.

Best results are obtained by eating one cake half an hour before each meal, or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk or fruit juices.

A new authoritative book: written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry, and therapy of yeast. A copy will be sent you free upon request. amination to an individual could not be made so long as he need make no sacrifice to get it, then a whole new start would have been necessary. Similarly, with record forms. A start was made with very elaborate forms so that no possibly useful data should be missed. As time went on, the forms were tested item by item and greatly simplified by the elimination of the unessential. Careful study was made of definite types of record systems with the hope that other agencies performing health examinations in the future might be able to make use of the results of this investigation with a saving of time and trouble.

The Health Group Analyzed

Up to January 1, 1923, 872 persons had been examined at the stations, of whom 113 were men, 413 women, and 346 children. Two hundred eighty-four examining sessions were held; the sessions were of two hours each. With the 872 persons examined and 293 revisits made by them, it was found that the average number of new examinees per session was three, and the average attendance per session, including revisits, was four.

In considering the social and economic standing of these examinees, it was found that 69.5 per cent of the adults were foreign born, 14.9 per cent native born of foreign parents, and 15.6 per cent native born of native parents. Among the children examined, few, of course, were foreign born, 8.1 per cent, the majority, 54.1 per cent being born of foreign parentage. By far the largest group of examinees were of Italian parentage, about 42 per cent; of the remainder, approximately 23 per cent were American stock, 12 per cent were Irish, 10 per cent Hebrew, 7 per cent Slavic, and 4 per cent German. The remaining 2 per cent included representatives of nine other races or national groups.

The fact that 95 per cent of the examinees were referred by nursing or social agencies is one of the chief reasons for low economic status as shown by the social records. Only 21 per cent of the group had adequate financial support, 54 per cent were "getting along" upon insufficient income, and 22 per cent were dependent upon relief from an outside source. Eighty per cent of the families were living under crowded conditions with less than one room per person.

The applicants examined, because of their poor physical condition and limited resources, have not permitted the fullest development either of the health examination or health instruc-

tion. Postural defects, flabby muscles, and even flat feet had to be ignored until existing disease processes or serious physical defects received attention. Only twenty individuals out of eight hundred seventy-two were found to be "normal," i. e., requiring no treatment or health direction.

Health advice was given in writing to all examinees requiring such regulations who were not referred elsewhere for treatment. Care was taken not to give directions in hygiene to those going elsewhere for treatment, since this might have been an interference with the doctor under whose care they were to go. Approximately 52 per cent of this health advice related to diet, including the drinking of water. Fourteen per cent of it related to exercise and fresh air, and 10 per cent to cleanliness.

The nursing service in the clinic consisted in assisting the doctor in taking blood for Wassermann and other procedures, as well as caring for his instruments and making routine tests of the applicant: temperature, pulse, weight, urine (sugar, albumen, specific gravity), hearing and vision.

The facts regarding the social and economic conditions of examinees have been provided by means of a record form which the agencies interested filled in previous to the examination. The necessary cooperation with social agencies for the follow-up gave further opportunity for the development of the social aspects of the preventive health work. To the social agencies that had referred their applicants to the stations, detailed reports of the entire physical condition of the applicant were rendered with reference to clinics, and the examinee himself was, whenever possible, stimulated to see himself through to complete recovery.

Portable Equipment

Certain facts have been gained from this experience regarding both time and cost of the examination as well as the necessary equipment. Our conclusions regarding cost are explained later. Regarding equipment, we found that the essential items are those usually provided in an office equipped for private practice. For purposes of convenience, this equipment has been fitted into a suit case (15x22x5) that can be carried from place to place. It contains sheets and one dozen examining robes, besides the instruments and urine outfit, and weighs about forty-seven pounds. Scales are not part of the usual port-

able equipment, but are generally found in schools, settlement houses, and other places where examinations might be made.

As to time, if the physician does everything, including the taking of the social and industrial history, and instructing the examinee, it takes him at the least one hour. Where the applicant comes with history prepared and tests performed, with the social worker to instruct the examinee, the minimum time is twenty minutes. There is marked personal variation both in the doctors' methods of spending time and the needs of the special applicants. It takes the doctor about half as long to find out what is the matter with an examinee as it does to record this and interpret it to the applicant. Elements affecting time are: The general intelligence of the examinees, their understanding of the language, the adequacy of their support, and the readiness with which they recognize the need for change in their habits.

A special effort was made to get information as to the extent to which the applicants needing treatment actually secured it. Since few could afford to pay for private medical service, nearly all of them had been referred to the dispensaries. The social agencies were in general responsible for the follow-up of cases and reports secured by our health stations from these agencies in every possible case. A special study of the experience of the patients in dispensaries is under way. Thus it is found that of 603 persons referred to the dispensaries, 368 actually went for treatment. Many of the obstacles in the way of their going will be suggestive to those interested in improving out-patient service, and it is expected to bring these out in a special report.

At the beginning of this experiment certain questions were in mind to which it is felt the health examinations thus conducted ought perhaps to give an answer. In considerable measure, this can now be done. For the sake of definiteness the conclusions thus far reached are stated under a series of nine headings:

(1) *Suitable Subjects for Health Examination.*—Health examinations are indicated for persons not obviously ill, having a financial margin to live above the bare necessities, and sufficient intelligence or imagination to be willing to exert themselves to improve their own condition. Experience indicates that persons who are below these financial or mental levels are chiefly benefitted through the discovery of diseases or defects rather

Sterilize everything in one simple unit

INSTRUMENTS, dressings and water—all are positively sterilized in the Castle No. 1512. It is compact, convenient and avoids make-shift paraphernalia. Furthermore it makes your nurses and doctors sure of their sterilization.

The famous Rochester Sterilizer steams (dry) the dressings at 212°. Instruments are boiled in the lower section. Every drop of water in the urn is sterilized, gauge glass included. Any heat. Send for more details of the Sterilizer that you will want.

than by the receipt of constructive advice for the promotion of health; for without financial margin there is small opportunity for personal development, and without intelligence or imagination the individual does not endeavor to carry out health advice and instruction.

Our experience with the socially dependent group has demonstrated that the majority of such persons require medical treatment. Need for constructive health work among this group is generally found to be secondary to the immediate need for medical treatment, and for the correction of physical defects.

The health examination is useful to such examinees in revealing medical needs, but its special functions of constructive work for the conservation and promotion of health are in such cases necessarily subsidiary because of the presence of active illness or of serious physical defects.

A modification in the type of examination particularly adapted to the client of the charitable organization has been developed. The emphasis here is upon the discovery of physical defects and diseases, and the nature of the treatments needed. It is not believed desirable, however, to limit the examination of such persons to a brief looking over to discover outstanding diseases and defects. A more complete physical examination is advantageous for this makes possible some appraisal of the examinee's physical assets.

(2) *The Health Needs of the Group of Persons Thus Far Examined.*—The examinations have demonstrated that nearly all of the examinees were in decided need of medical treatment or of hygienic advice, or of both. Out of 970 persons examined, but 603 or 62.2 per cent required medical treatment; 343 or 35.4 per cent needed hygienic advice and guidance, but not immediate treatment, and 24 or 2.4 per cent were regarded as "normal," needing neither advice nor treatment. In the children's group the percentage needing medical care was about the same but the percentage found normal was higher.

The medical significance of these findings will be interpreted in a special article of a more technical nature. The outstanding defects found were those usually apparent in medical examinations—dental defects, errors of vision, diseased tonsils or adenoids, and defects of posture and hearing being the most noticeable in the order named. Of diseases or abnormal functions, the outstanding ones were malnutrition, constipation, and cardiac

diseases. Eighty-five cases of laceration of cervix or perineum, and fifty-seven cases of uterine defects or diseases were found among the 413 women examined.

(3) *The Relation of Health Examinations to Private Medical Practice.*—Health examinations reveal a large number of conditions requiring medical treatment. The persons who, as above defined, are most suitable applicants for health examinations, will usually call in private practitioners to care for these needs. The health examinations themselves offer opportunities for physicians to give service and receive compensation.

(4) *Technic of the Health Examination as Compared with the Usual Medical Procedure.*—Any well trained physician can learn to make the needed examination but to be successful or effective from the patient's point of view the physician must be as much interested in promoting health as in treating disease. Many physicians experience difficulty in devising suitable directions for examinees in relation to needed modifications in habits. This is largely due to the fact that detailed knowledge of the relations of habits to health has not been formulated.

(5) *Medical Scope of the Health Examination.*—A health examination is an examination of a person by a physician for the purpose of appraising the degree of bodily efficiency or well being, of indicating weaknesses or defects, and of advising hygienic and remedial measures.

A health examination must, therefore, include the careful physical examination of the body, and also inquiry into the occupation, habits, personality, and home environment of the individual.

The health examination is thus best performed by a doctor who stands to the examinee in the relation of family physician; otherwise, time must be taken by the physician to inquire with special discernment into those aspects of the patient's personality, occupation, habits, and environment with which the family physician would be familiar.

The purpose of the examination being to promote better health as well as to suggest steps towards remedying any existing defects or diseases, the examination should lead to advice to examinees regarding: (a) Treatment, if any, needed for existing disease or defect; (b) hygiene of life, particularly diet, occupation, sleep, exercise, and recreation.

Advice resulting from the health examination should be given to the

examinee *personally* by the physician. All laboratory, x-ray, or other tests, and all reports of findings by any specialists who have been called upon in connection with the examination, should be considered and interpreted by the physician, who then gives the examinee advice under the two headings (a) and (b) above.

It is not desirable that any written statement of medical findings be given to the examinee unless put in such terms as to be clearly understood by the examinee in its practical significance to himself. Technical statements should be given only to a physician who may be called upon to give the person treatment. A written memorandum of instructions to the examinee of things which he should do is generally useful as a supplement to the verbal instructions.

(6) *Cost of Health Examinations.*—These examinations have been undertaken from the research point of view and this has added considerably to the cost. A good deal of time has been spent in making arrangements with patients, securing information from them, making connections with the organizations or persons through whom needed medical treatment would be provided, and this has added substantially to the salary charges for non-medical assistance. On the average our examinations during this year's experience have cost \$5.69. No allowance has been made in this figure for broken appointments, for rent, heat, light, cleaning of quarters, etc., as these have been in every case provided by an agency without charge. Initial cost of professional equipment is not included.

This figure is based upon our original rate of payment for the medical service, which was five dollars per session of two hours. It was our plan, however (which has been carried out) to increase the payment to eight dollars per session after the physician had been with us for one year. This increase has raised the expense for the medical service, but is somewhat counter-balanced by a reduction in the cost of clinic management, for physicians accustomed to the work can do more within a given time, and require less assistance.

During the past year it was found that of the total expense the payment for medical service was 29 per cent, maintenance of equipment 6 per cent, while the remaining 65 per cent went for non-medical salaries, i. e., nursing, clinic management and clerical help. With the increase in medical fee and greater facility on the part of the physicians and less non-medical assis-

Judge a Medicinal Mineral Oil by its Viscosity

BAINBRIDGE says, [Women's Medical Journal], "Liquid Petrolatum [medicinal mineral oil] is the agent which by common consent is pronounced the most satisfactory in the treatment of chronic intestinal stasis. - - - Some products are too thin, and consequently give rise to "dribbling", which is not only extremely disagreeable, but defeats the purpose for which the oil is given.

The London Lancet states that "oil of too easy fluidity [low viscosity] frequently has a disturbing effects upon the digestion."

Stanolind Liquid Paraffin [Heavy] — Tasteless, Odorless, Colorless—is a new medicinal petroleum product. It is a mineral white oil of ideal viscosity for the treatment of intestinal stasis.

Stanolind Liquid Paraffin is rich and heavy-bodied, and has specific gravity of 0.891 to 0.895 at 15 degrees C [59 degrees F]. Its viscosity is 300-310 Saybolt at 37.7 degrees C [100 degrees F].

Judged by its viscosity, as well as by its specific gravity and its absolute purity, Stanolind Liquid Paraffin [Heavy] meets the most exacting requirements of the medical profession.

STANOLIND LIQUID PARAFFIN

(Heavy)

TASTELESS — ODORLESS — COLORLESS

Produced by Standard Oil Company [Indiana], 910 South Michigan Avenue, Chicago

tance, these percentages will be substantially changed with consequent increase in the proportion opposite physicians' salaries. Where the scope of the examination is reduced because the outstanding problem is the discovery of disease and defects, to which constructive health advice is necessarily subsequent, a simpler type of record and a briefer period of examination is possible with corresponding reduction in cost. Where the examinees belong to an organized group of some kind so that the staff for receiving them, securing information from them, and assisting in the carrying out of instructions can be reduced to a minimum, the cost would be still further lowered. We would estimate that the cost of an examination at the salaries above indicated would vary between \$2.00 and \$6.00, depending upon the conditions indicated. We hope during the present year to work out specifications of the expense of types of examinations adapted to various requirements. The above figures are tentative.

(7) *Auspices Under Which Health Examinations Should be Conducted.*—

(a) *Private practice.*—It is believed that the main resource for health examinees among the general population should be the private practitioner of medicine. (b) *Medical institutions.*—For those unable to pay private fees or needing special study for which laboratory, x-ray, or the consultation of specialists is required, health centers serving defined areas, or health clinics organized as divisions of out-patient departments of hospitals, are necessary. (c) *Health examinations* would seem to be a suitable form of preventive work in which the municipality may well engage through its health department. They would also seem a proper field for support by private health agencies and for development by life insurance companies and large business establishments, particularly during the present period of experiment in methods of such examination, and until public understanding and interest is sufficiently active and stable to insure sufficient municipal appropriations.

(8) *Best Locations for Health Examination Centers.*—Large general dispensaries should include health examination clinics, but experience indicates that in order to reach any considerable proportion of those needing health examinations, local stations are also necessary. As with other forms of preventive work, utilization of an opportunity by the mass of the population is greatly facilitated by proximity to the home.

(9) *Health Examinations for the Clients of Charitable Societies.*—Examinations conducted at the central office of each society would require its clients to come from all parts of the city, and would present great practical difficulty, besides the expense of transportation and escort. Local stations maintained by each society independently will usually be on too small a scale and under too little expert medical supervision to give maximum efficiency and economy.

Local stations providing health examination service for the clients of charitable organizations, would be the most economical and efficient method of meeting the need. Cooperative financial participation by charitable and health organizations in maintaining such examination centers may be indicated for some districts, while in others, arrangements for special examining clinics in the out-patient departments of hospitals may be the preferable plan.

Rhode Island Mental Hygiene

INADEQUATE facilities at the Exeter School for the Feeble-minded, insufficient provision for the identification and special training of the mentally defective children in the public schools, and the urgent need of a state psychopathic hospital are the outstanding features of the Report of the Mental-Hygiene Survey of Rhode Island, conducted by the National Committee for Mental Hygiene. The survey conducted under the supervision of Dr. Samuel W. Hamilton, director of the Division on Hospital Service of the National Committee.

The parsimonious attitude of the state toward the Exeter School for the Feeble-minded established in 1907, has not permitted the institution to function other than as a custodial asylum.

The institution is greatly overcrowded and its activities are interfered with by the presence of beds in every available space—even in the school building where but two rooms remain for teaching purposes. The superintendent is the only physician on the grounds and must, in addition to his executive work, care for all cases of physical illness. There is but one academic teacher. Such manual and industrial training as is given is by untrained teachers. Vocational training is not possible because of lack of funds. There is great difficulty in securing attendants on account of low salaries and inadequate living quarters. The fire risk is great. There is a waiting list of two hundred. In the meantime, the state is finding it necessary to care for, in institutions not designed for them, a total of 232 mental defectives, or about 70 per cent of the number at the Exeter School.

The state program for mentally defective persons advocated by the report is briefly:

(1) Examination and registration of all school children who are seriously behind their grades and of all

children who are excused from school attendance because of mental handicaps.

(2) Provision in every school system for special training to be given those who cannot profit by the regular school curriculum.

(3) Continued supervision of mentally defective persons, whether or not they have been in state institutions.

(4) A law permitting certified mental defectives to leave school at the age of fourteen and receive industrial training under state supervision.

(5) Legal recognition that mentally defective individuals are throughout life wards of the state and entitled to protection.

The following changes in legal provision as pertaining to the insane are advocated; simplification of the commitment procedure, so that persons needing treatment may not be denied treatment on account of cumbersome legal requirements; provision for commitment for observation on the certificate of two physicians; provision for emergency admission for a period of ten or twelve days; abolition of the requirement that the patient must appear in court; arrangement by the hospital and not the police for the transportation to the hospital of a patient committed; and by broadening of the voluntary admission law.

The report further recommends a travelling clinic for the examination of the school children of the state, and a follow-up system whereby supervision and guidance would be afforded the pupils needing such care.

An increase in accommodations, personnel, salaries, and the construction of a separate building for insane prisoners are some of the needs of the state hospital.

A more detailed account of the survey and recommendations is contained in the *Mental Hygiene Bulletin*, April, 1923.

4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

Why Not Provide Your Men With Sanitary Drinking Equipment?

THROUGHOUT your plant are "safety first" posters, telling your men what not to do.

If you instructed them not to drink contaminated water, could they comply with your request?

Inventory any insanitary drinking equipment today. Install **HALSEY TAYLOR Cooler Fountains**, one to each 25 men, and note the greater energy each man puts into his work. Note how time off for sickness is cut to the minimum, and time loss for drinking is decreased materially.

Tests by large corporations have proved that **HALSEY TAYLOR Cooler Fountains** are more efficient, due to the automatic stream control, the practical drinking mound and the superior cooler design.

Write today for 32-page catalog and prices.

Public Health in the College Curriculum*

IN ORDER that all students as individuals may learn to live healthfully, efficiently, and abundantly and in order that they may later assume their part as leaders in the community, it is recommended that a one- or two-semester course in personal and community hygiene of approximately three hours per week be required of all first year students.

In addition, a required course in biology for freshmen students is advocated by some administrators.

The course in personal and community hygiene should be in charge of an instructor whose chief interest is health education in its broader aspects and who has had special and recent training in this field. This person may be the professor of hygiene, public health, physiology, biology or physical education; the gymnasium director or athletic coach is not likely to be a suitable person. The course should not consist merely of a symposium of lectures; it is particularly undesirable to bring in a number of practising physicians to lecture on their various specialties.

In the development of that section of the course dealing with personal hygiene, it is necessary to use particular care, if desired results are to be obtained. In the colleges of the United States, there is at present a wide variation in the effectiveness of personal hygiene instruction. The course should deal with various health problems revealed by the physical examinations at the beginning of the freshman year, or by periodic examinations in colleges where they are given. The mere imparting of information in such a course is insufficient. A student may be fully informed in regard to disease and its prevention and yet conduct himself in such a way as to contract specific diseases or gradually to deteriorate in health if motivation for the development of proper health habits has not been provided. It is important to show the relation between healthful living and ef-

ficiency and happiness, and health ideals must be developed. It is also important that living conditions, physical exercise, study program and health supervision should be such that the students while in college may establish correct habits of living.

The second section of the course dealing with community hygiene should have the same careful attention as the first half. Through proper teaching in this field, colleges and universities may produce leaders in civic life who will be effective in developing better health work in municipal and state governments.

Education for Health Work

The selection of courses by those students who plan to enter public health work as physicians or as sanitary engineers will be determined by the requirements of schools of medicine, public health, and engineering. Increasing numbers of students, however, are entering public health work without a medical or engineering degree. Some of these will seek minor positions immediately upon obtaining the A. B. degree. Others will take graduate work for the A. M., M. S., C. P. H., Ph. D. or other higher degree.

In general, it is desirable to provide for such students a solid foundation of courses in the basic sciences, particularly general biology and physiology, for the first two years. Because of the increasing attention being given to the economic and sociological aspects of public health work, one or more courses dealing with the basic principles of sociology, or "social economics," should be included; a course in social psychology—preceded, if possible, by a course in general psychology—will also be very useful as a basic subject.

During the last two years of undergraduate work, vocational subjects may be provided. Under such a plan, the student who in his third year may decide to become a bacteriologist will have had during his first two years a background in biology, physics, chemistry, and mathematics; then in his last two years he will be able to specialize in bacteriology, immunology and serology. Similarly, should there be provided during the third and fourth years various vocational courses for those planning to enter the

fields of vital statistics, public health education, dietetics, physical education, hospital social work, and public health nursing. This plan is already in effect in numerous colleges and universities.²

Those who do graduate work in preparation for service in these various fields will be able, of course, to select additional courses which will broaden their background and afford them a more thorough knowledge of the fields in which they specialize.

Sneeze Gas as a Suicide Preventive

"They will sneeze themselves back to life," said Gen. Amos A. Fries of the chemical warfare service, when he told at the meeting of the American Chemical Society at Yale of a new sneeze gas compound that can be used in illuminating gas to prevent suicides or accidental deaths from gas poisoning.

Diphenylchlorarsin is one of the suicide preventives. If you cannot pronounce that try "diphenylaminarsin." These were used in the war. There is another one now being developed in the chemical warfare laboratories that is a worse sneeze producer and yet is less poisonous. Add only one part in 10,000,000 of gas and no sleeper, no matter how intent on self-destruction, will be able to stay in the gas-filled atmosphere long enough to die, said Gen. Fries. But when the illuminating gas is burned the sneeze gas goes up in smoke and becomes harmless. There is therefore no danger of the air being badly polluted except when the dangerous unburned gas is escaping.

Gen. Fries predicted that if gas companies adopted and developed this peacetime by-product of chemical warfare, that suicides and accidental deaths due to gas will greatly decrease. There has been a marked increase in accidental death due to the increased use of small gas heaters that have no flue connections. When these burn ordinary gas, a tasteless, colorless, odorless intensely poisonous gas, carbon-monoxid, is poured into the room. Sneeze gas will act as a respiratory red flag and make this dangerous stuff detectable. No tenable objection can be made to its use and the interests of all would be served.

*This report on Courses in the College Curriculum Dealing with Public Health is recommended by the Surgeon General's Advisory Committee on the Education of Sanitarians which is composed of the following members: D. L. Edsall, chairman; C. E. A. Winslow, vice-chairman; A. J. McLaughlin, secretary; A. C. Abbott, C. C. Bass, Haven Emerson, W. H. Howell, E. O. Jordan, William H. Park, W. S. Rankin, Wickliffe Rose, M. J. Rosenau, F. W. Sears, John Sundwall, C. E. Turner, Henry F. Vaughan, Victor C. Vaughan, William H. Welch, Ray Lyman Wilbur, E. G. Williams, and Linsly R. Williams. The members of the Subcommittee participating in the preparation of this report include: Maurice A. Bigelow, Robert E. Chadcock, Donald W. Davis, A. T. Poffenberger, Wickliffe Rose, Isabel Stewart, John Sundwall, C. E. Turner, Jesse F. Williams.

AN examination of some of Sherman's Vaccine* prepared *Ten Years* ago showed no apparent deterioration nor autolysis.

We welcome microscopic comparisons of our vaccines, for,—freedom from deterioration and autolytic products, accuracy of count and morphological characteristics.

Bacteriological Laboratories of G. H. SHERMAN, M. D., Detroit

*This vaccine was in druggist's stock in the regular way and recalled as outdated.

A Valuable Aid to Better Health

The VIT-O-NET Electrical Magnetic Blanket

is proving unusually helpful to those interested in promoting better health. Endorsed and used by leading physicians, hospitals and health authorities. Creates a general elimination through pores and other waste channels, without any weakening effect. Its dry electrical magnetic heat penetrates deeper than any other form of heat—with more effective results. Especially valuable for treatment of Rheumatism, Bright's, Auto-Intoxication, Arthritis, Eclampsia, Pneumonia and all diseases caused from congestion of waste and poison not eliminated and poor circulation. Also invaluable for nerve shock. Far superior to ordinary hot pack methods. One or more of these appliances needed in every hospital room.

Complete interesting facts on request.

Nutrition Work in Arkansas

IN the south central part of Arkansas there is located, along the banks of the Arkansas river, the third city in the State in population, but not in progress. Jefferson County, of which Pine Bluff is the County Seat, is in what might be termed, the middle of the Arkansas "Black Belt." In fact, the negro population outnumbers the white some ten per cent. From this one can readily see that the Public Health problem is unique.

At the close of 1921 nutrition work in the public schools was an unheard of innovation. In January, 1923, there were fourteen white nutrition classes, and two negro classes in operation, under the auspices of the Jefferson County Tuberculosis Association.

The results obtained from the inauguration of these classes has been most startling and to those not cognizant of nutrition work, the results are almost beyond comprehension, according to information received from Miss Virginia Misenhimer, executive secretary of the Jefferson County Tuberculosis Association.

In February, 1922, one school had a total of seventy-two per cent underweight children; in December, 1922, the total was fifty-two per cent, showing a reduction of twenty per cent. In a school where no classes were conducted, the total percentage remained the same.

After the work in the white schools had been thoroughly established and practical results obtained, attention was turned to the negro population. In selecting children for negro classes, the weight record determined who shall enter. The majority of these entrants are ten per cent or more underweight. A practice is made of selecting a few children for the class who are free to gain and who are not so much underweight, because we have found the diploma, plus the ceremony of graduating, stimulates the child, to continue his efforts.

Each child has a thorough physical examination including blood tests for malaria, and tests for intestinal parasites. In the recent physical examinations made, no malaria or hookworm was found, but a number were listed as tuberculous or "suspects."

The examinations are made gratis by private physicians of the city and with the aid of the state laboratory, an effort is made to find the cause of underweight in each child.

The individual weight chart creates much rivalry and the keenest interest is displayed in the race for the gold star.

In teaching the young children we use health stories, health songs, caricatures and bi-monthly compositions on health. In addition each child who belongs to the nutrition class is enrolled in the Modern Health Crusade.

For two years the Crusade was placed among the entire student body, but for lack of additional workers, plus the manner of living of the majority of our negroes, the Crusade did not produce satisfactory results.

In place of the Modern Health Crusade, we have used leaflets containing questions and answers on tuberculosis and malaria. This method of instruction so far has proved very satisfactory.

For various reasons, the work among the negroes will be somewhat limited for a number of years, but in view of the fact that the local board of education has incorporated the public health program as a part of the school program, an era of general success in our propagation of social and health education is anticipated.

Course in Medical School Inspection at Columbia

A course in the principles and practice of medical inspection of schools and school children will be offered to physicians at the School of Medicine of Columbia daily from 10 to 12 a. m., except Saturday and Sunday, during the six weeks of the summer session (July 9-Aug. 17).

This post graduate course (Equivalent to six points in Academic Credit) in one of the most important functions of public health service is designed to meet the requests of physicians now engaged in Medical School Inspection under Boards of Health or Boards of Education, on whole or part time basis, who wish to equip themselves better for their work, and prepare for advancement to positions of greater responsibility, and to provide appropriate instruction to those who wish to enter this field of administrative medicine.

The instruction, which will be provided by lectures, demonstrations, practical exercises, class discussions, and preparation of individual reports on selected topics, will be given by a number of especially qualified persons, physicians, school administrators and others, under the direction of Dr. Haven Emerson.

The following main divisions of the subject of Medical School Inspection will be dealt with in detail: School sanitation; medical examinations of school children; communicable disease control; psychiatric problems of school age; preventable defects of eyes, teeth, heart, posture, and nutrition; health education in schools; and administrative problems of doctor, nurse, and teacher.

Not so long ago nutrition work anywhere in Jefferson County was an innovation. In 1921, fourteen white nutrition classes were conducted, and two were carried on exclusively for negroes.

"Superior to Digitalis"

(This is *not* a drug advertisement)

WHEN such an authority as Hobart A. Hare, Professor of Therapeutics, Materia Medica and Diagnosis, at Jefferson Medical College, Philadelphia, says in his *Practical Therapeutics*: "So useful is caffeine in cases of cardiac disease that it has largely supplanted digitalis in the hands of some practitioners"—

When another equal authority, A. A. Stevens, Professor of Applied Therapeutics at the University of Pennsylvania, says in his *Therapeutics*: "In the circulatory failure of acute infections, such as pneumonia, influenza, typhoid fever, etc., the action of caffeine is at times superior to that of digitalis"—

And when another equal authority, Oliver T. Osborne, Professor of Therapeutics at Yale University, says in his *Therapeutics*: "Caffeine is

quickly absorbed and acts quickly and it should be remembered that caffeine is as well administered in the form of strong coffee as in any other way"—

—you can appreciate that Coffee is much more than a pleasant beverage; that it is a general article of diet which you can frequently turn to good account in case management.

The thinking physician of to-day recognizes this and does not thoughtlessly strike Coffee from the menu without *clinical indications*. He does not *unnecessarily* take from his patients an appetite excitant, an aid to digestion, a peristaltic stimulant.

To most Americans, Coffee is as essential to the enjoyment of breakfast as the morning paper. Don't take Coffee off the breakfast table without diagnostic indications.

Woman Heads Health Department

By the recent appointment of Miss Gertrude M. DeWitt as its health agent the city of Chicopee can lay claim to the unique distinction of being the only city in Massachusetts and probably in New England with a woman as the administrative head of its Board of Health.

Public Health Conference

A highly successful conference was held at Springfield, Mass., April 26-28, with Dr. Kelley, state commissioner of health as chairman, and with a representation from sixteen participating organizations representing all the various voluntary health forces of the state. The program covered reports on the work of the various co-operating organizations with special sessions dealing with, Red Cross Health Work, the Tuberculosis Program, the Mental Hygiene Program, the care of Infant Paralysis, Rural Health Work, Public Health Dentistry, Public Health Nursing, and School Health Work. A special committee was appointed to consider the possibility of issuing a joint health bulletin including the various health organizations of the State and also the possibility of opening joint offices for the various health associations in Boston.

The revenue in 1919 for soda beverages was the greatest in history. The consumption of mineral and soda waters has shown an increase from \$58,400,000 in 1914 to the sum of \$115,577,000 in 1921, according to figures compiled by the census bureau. The trade in 1919 was valued at more than \$135,340,000. This includes all kinds of carbonated and fruit beverages, ginger ale, and other so-called soft drinks, but does not include natural spring water.

Fellowship in Psychiatry

As a result of a gift from the Commonwealth Fund to the National Committee for Mental Hygiene, the Division on the Prevention of Delinquency has a fund for fellowships in psychiatry. Those securing fellowships will be placed under training in the clinics now being conducted by this division. The object of the fund is to prepare properly qualified psychiatrists for positions in connection with permanent clinics that are now being organized through the activities of the demonstration clinics conducted by the National Committee for Mental Hygiene. The fellowships will be awarded by a committee composed of Dr. Thomas W. Salmon, Mr. Barry C. Smith, and Dr. Frankwood E. Williams. Those interested in securing information regarding the fellowships may address Dr. V. V. Anderson, director of the Division on the Prevention of Delinquency, the National Committee for Mental Hygiene.

Millions in Refuse Thrown Away

Fire Chief John Kenlon, after a survey of refuse disposal methods in many cities of Germany, France, and other parts of Europe, has recommended in an extensive report to Mayor Hylan that New York's refuse be burned, says the *New York Times*.

The conclusions of Chief Kenlon coincide closely with the conclusions of others. A committee acting for the Merchants' Association has made a study of the question and recommended a zone incinerator plan whereby all the refuse of New York would be burned. John McEwen, sanitary engineer, after an independent study of the subject, has recommended the same thing and offered figures to prove that New York's waste disposal system could be made to pay for itself and return an income.

The incinerators used in Rotterdam, Zurich, Frankfurt, and many other European cities burn everything to a hard clinker, the value of which for concrete is said to equal or exceed that of broken stone. Crushed stone in this country, used in ordinary concrete construction, costs from six to eight times the production cost of this incinerator clinker, which would create a source of income to the city.

The Public Health Committee of the New York Academy of Medicine has just made public a report, according to which New York's refuse material has now reached a total of 3,705,000 tons annually. The report says fur-

ther that the total cost under the present system to the city of caring for this waste is twenty million dollars a year. Almost three-quarters is ashes. Rubbish of one sort or another comes to 270,000 tons; garbage, 440,000, and street sweepings, three hundred thousand tons.

In New York, according to the Featherstone report in the transactions of the American Society of Civil Engineers, the refuse contains a heat value as high as 30 per cent of coal. Thus the 3,000,000 tons of waste would have the heat value of nine hundred thousand tons of coal. Transformed into power this would mean six million dollars a year.

Correct Menus for School Children

A good mark in school often depends less on how hard a child studies than on what he is eating, say specialists in home economics at Cornell. Especially is this true in cold weather when the right food is necessary not only to supply the energy for play and other activities, but for keeping warm.

The following is offered as a satisfactory daily menu:

For breakfast, orange, prunes or dried apricots, oatmeal, a wheat cereal or cornmeal; there should be milk or weak cocoa and toast, preferably of whole wheat bread.

For dinner, the main dish may be macaroni and cheese or an egg, or—two or three times a week—a small serving of meat, a baked potato, buttered carrots, onions, beets or a green vegetable, whole wheat bread with butter, a baked apple and milk.

It is better for a child to have dinner at noon than at night; in case, however, the noon meal must be hurried so the child can get back to school, the supper menu should be given to the child at noon, and the dinner menu as early as possible at night.

For supper, a cream soup is especially good in winter; cream of potato, carrot, celery, spinach or bean soup are also recommended. For a vegetable, celery or buttered onions or tomatoes may be served, with whole wheat bread and butter. For dessert, there may be baked custard or rice and raisin pudding or stewed fruit, with oatmeal or ginger cookies and, of course, milk.

Changes may be made in all these menus; for instance, a variety of fruits and vegetables may be chosen, but the general plan should be held to closely.

The School Architect's Problems As Related to Public Health

*The School Is Now a Going Concern, Not a Static, Crystallized Institution
and Modern School Environment Leaves the
Children Free to Grow*

By W. G. ECKLES, ARCHITECT, NEW CASTLE, PA.

DURING the last few decades the practice of architecture has become wonderfully complex. The designers of earlier buildings were principally concerned with the questions of construction and design. Modern civilization, however, has accumulated many wants that must be satisfied at great expense and much study. In no branch of architecture have these changes been greater than in planning and building the modern public school.

The requirements of plumbing, heating and electric equipment are each so important in modern school work as to require expert engineering knowledge for their proper planning and installation. Domestic science, manual training, physical education, cafeteria equipment and all such new and modern departments also require most careful study, much apparatus, and special equipment.

The fundamental requirements of lighting and ventilation have become

pretty generally agreed upon and most states have enacted legislation fixing the minimum requirements, but even in these there is still a marked tend-

formerly twenty-five to twenty-eight feet was a standard practice. The benefits from this are principally that a much more uniform illumination is obtained. With the wider class room the pupils occupying the inner rows of seats were at a distinct disadvantage. Much greater attention is also being given to the matter of efficient artificial lighting, made necessary by the increasing use of school buildings for night school. The proper working out of these problems greatly reduces the eye strain affecting both pupils and teacher.

In the matter of heating and ventilating the principal improvements have been in the general adoption of the indirect method merely for ventilation purposes and the use of direct radiation under or near the windows for heating purposes. Under the older method of purely indirect heating there was a tendency to overheat the air and the room was often unevenly heated. Under the divided system the

A good demonstration is given here of the effectiveness of overhead lighting for gymnasium work.

ency to improve these more or less standardized requirements. In lighting this takes the form of narrower class rooms, preferably twenty-two or twenty-three feet in width, while

radiators at the windows overcome the heat losses and secure an even temperature throughout the room. Both the direct and the indirect radiators should have automatic control. Some of the devices for humidifying and washing the air have been quite successful and where used are a distinct advantage both in the matter of health and in general operating costs. Recent study of the heating and ventilating problem shows that merely heating the room to a given temperature and supplying a certain amount of fresh air is not sufficient. It is shown that the most important point in connection with healthful atmospheric conditions is not necessarily low percentage of carbon dioxide in the air but rather the humidity as measured by the wet bulb temperature. This subject is being well covered in the series of articles by Dr. E. Vernon Hill in the *Heating and Ventilating Magazine*.

Increasing attention is being paid to the matter of simplifying the amount of travel between the various portions of school buildings. In all schools the tendency is to dispense with the expensive and unsatisfactory basement and, where the size of the lot will permit, to confine the height of the building to the main floor and second floor. Many grade buildings are successfully planned, one story high, with the central hall expanded into a large play room with a stage in one end entirely dispensing with stairways. This idea in being applied to two or three story junior and senior high schools takes the form of a central auditorium on the ground floor with a gymnasium immediately back of the stage and with the corridors immediately adjoining, leaving out the expensive and old-fashioned light courts, the light for the auditorium coming entirely from overhead. The advantages are a considerable saving in first cost, greater conveniences, a more attractive appearance, and a very considerable lessening of the travel between the various parts of the building with less difficulty in going from one floor to the other. This method necessitates overhead lighting for the

auditorium and often the gymnasium, which has been found to be very satisfactory and entirely practical.

Of all the modern developments of school work perhaps none is of such

A good swimming pool is the most popular thing about a modern school and incidentally gives the best exercise.

wide-reaching importance to the community as the teaching of the household arts and the serving of noonday lunches. The latest high schools have been equipped with the most complete provision for the teaching of domestic science, sewing, laundry work, and the demonstration of proper housekeeping methods by the furnishing and equipment of a model housekeeping suite including entrance hall, living room, dining room, kitchen, bedroom, and bathroom. The influence that goes out from the teaching in these departments is very far reaching among all classes. Its value is most

day and increasing the use of the building and the efficiency of the investment in the plant. Under the old plan of operation the high schools were operated from 8:00 or 8:30 until 12:30 or 1:00 p. m. This made a long forenoon session, a late lunch hour, and a very much hurried program, with consequent strain on the nervous systems of both pupil and teacher. The new method permits the lengthening of the day so that all periods can be made a part of the school program giving the pupils opportunity for class meetings, athletic instruction, and the many special activities which have so entirely changed the social atmosphere of the modern high school for the better.

These lunches are furnished and served usually under the direct supervision of the director of domestic science and household arts and of the most simple and wholesome ingredients and practically at cost. Incidentally, the pupils are taught the use of proper and inexpensive diets thus helping to spread the good influence of the domestic science department to any pupils not taking instruction directly from that department. The cafeteria, where properly administered, is used by the very large majority of the pupils, at least in part, and greatly assists in stimulating the social activities as well as helping in the administration of the regular curriculum.

No modern school can be considered entirely equipped without a medical inspector's room, a dental clinic room, and, if of any considerable size, should also have a nurses' room with a complete equipment for first aid. These three rooms should be combined in one suite with an outer waiting room with northern light and convenient to both the gymnasium and the necessary outside athletic field.

Where the funds of the district will permit, all high schools, at least, should have a complete standard swimming pool, with adjacent shower and locker rooms for both pupils and directors. Nothing in the school activities relating to health and to the

An attractive shop building planned as a separate unit. In this shop the plan, lighting, and equipment are identical with the best practice in the most modern factories.

helpful, of course, in the Americanization movements for children of the foreigners in industrial communities.

Of not less importance is the modern cafeteria. This was first adopted as a means of lengthening the school

(Continued on Page 417)

Recreation in Hospitals and Its Therapeutic Values

When All Motor Activity Means Individual Expression, Work Becomes Play, and All Play Recreative. Who Knows How Much of Our Boasted Intellectuality Is Muscular Sense?

BY R. K. ATKINSON, DIRECTOR, RECREATION IN INSTITUTIONS, RUSSELL SAGE FOUNDATION, NEW YORK CITY.

DURING the past thirty years a new attitude has arisen in regard to the legitimate use of play and recreation, and today there is general recognition of the necessity for facilities and leadership for play activities for all sorts and conditions of people. The first interest in this subject no doubt arose from a recognition of the developmental value of play for children. Progressive thinkers on educational subjects, as far back as Pestalozzi, Fröbel, and Herbert Spencer emphasized this, and for a generation or more there has been constantly increasing attention to the theoretical and provision for the practical aspects of the play movement.

In its practical aspects the play movement may be considered as one detail of the modern social progress movement which, expressing a desire for human betterment in a multitude of ways, could not fail to see the great constructive social gain in providing a place for play and suitable leadership to create and carry on play traditions which were rapidly being lost in the changed environment of our industrial civilization.

The play and recreation movement, arising from a fuller recognition of the rights and demands of childhood, soon created an appreciation of the fact that people of all ages and conditions are interested in recreation. Very soon after the beginning of the

playground movement we see the rise and growth of the movement for wider use of the school plant, for the establishment of social centers, the extension of park facilities, and the ac-

improvement have found great value in recreation for enriching and stabilizing lives which at best hold little of satisfaction or enjoyment. Programs have been developed which make use

of all sorts of recreational activities, including music, motion pictures, dancing and all sorts of dramatic entertainments, and in many cases physical activities and games in which large numbers have participated both actively and as spectators.

The more progressive institutions, however, have been increasingly unwilling to pronounce defects irremediable or to classify their cases as incurable, and have used recreation not simply to relieve monotony and to make life a little more enjoyable, but also

Particularly in the blind does the acquisition of muscular control mean increased mentality and mastery of their otherwise unexplored environment. The Pennsylvania Institution for the Instruction of the Blind has achieved through dancing the means of expression which made possible the presentation of "A Midsummer Night's Dream." This is the final dance of Titania, Oberon, Puck, and Fairies accompanied by the singing of Clowns in the background.

ceptance of the responsibility by the municipality and the state for providing and supervising legitimate leisure time activities for all of the people.

Those who are dealing with subnormal and abnormal conditions as they affect human relations were not slow to catch the spirit of the recreation movement, and institutions of all sorts have for a number of years given a definite place and an enthusiastic recognition to wholesome recreational activities. Even those institutions which accept only custodial responsibilities and which care for those for whom they can expect very little in the way of physical or mental

after some years of careful experiment are attributing to it a real therapeutic value.

Those who are taking this view think of recreation in very broad terms. They recognize the relation of physical activities to health of mind and body, and that it is largely upon physical activities that wholesome health habits are based, and through which we may secure even in highly abnormal conditions a better approximation to the normal functioning of the entire physical organism. A recent article by William H. Burnham of Clark University says: "The modern study of psychology and mental hygiene has put a tremendous em-

phasis on the significance¹ of the various forms of motor activity, and especially what we call physical exercise. Its educational, mental, and moral significance is greater than any, except perhaps a few of its most enthusiastic devotees, have imagined."

There is a real danger, however, in limiting recreation to "exercises." Those who recognize its therapeutic value include in their program a great number of artistic and esthetic interests and activities which although far removed from our older ideas of physical training are distinctly motor activities and are legitimately classed as recreational. They are demonstrating the possibility of using recreation, conceived in this broad and inclusive way, as a wholesome and practical means of stimulating, directing and training the individual in those mental and social attitudes which we are increasingly recognizing as so vital to his welfare and rehabilitation.

We must catch this larger significance of the mental and spiritual values in recreation if we are to appreciate it fully.

There is no need to point out or emphasize the large contribution which has been made in recent years to the treatment of the insane through occupational activities. The technique of the subject has been rather well developed and no institution can fairly claim to be doing its full duty by its patients unless it makes provision for occupational activities for at least a certain proportion of them. This type of work is being recognized and prescribed by medical officers in the hospitals just as definitely as is any other sort of treatment.

The success of occupational therapy is largely measured by the attitude of the workers who are responsible for its administration. The greatest success has been attained in those cases

where there has been a large recognition of its recreational content. One of the pioneers and leaders of the movement stated recently that occupational therapy cannot hope to succeed unless those who are in charge of it have some conception of the broad human aspect of their task, and cited the instance of a remarkable teacher who failed utterly in dealing with the insane because she lacked this approach.

This is the very spirit of recreation—understanding, sympathy, a sharing of life. All who deal with the insane recognize the necessity of this and those who are most interested in

in regard to work is often in need of careful analysis. There is no virtue in drudgery for any type of individual, and work readily becomes drudgery when routine activity has drawn out of it all of the soul stirring interest; but if into our work we can bring a spirit of wholesome recreative play it ceases to partake of the spirit of drudgery. Thomas Edison, who has throughout his life time been known as an industrious worker, said upon his seventieth birthday, "I have never done a day's work in my life. It has all been play." If we compare the attitude of this worker and the spirit which he has been able to bring to his

work with the lot of the average worker, who in our great industrial organization tends more and more to be a mere cog in a vast machine, we will understand something of the reason for the great increase in dementia praecox. As our civilization becomes more and more highly organized, its labor saving machines are often deadly to those who serve them.

There was a time when one's daily work provided a wholesome outlet for the emotions and gave opportunity

for self-expression. With increasingly large numbers of workers this opportunity no longer exists. As life is narrowed to the limits of a machine governed civilization, it is small wonder that mental disorders increase. If the conclusions of at least one group of the psychiatrists are based upon good reasoning the relation between mental disorders and our lack of opportunity for self-expression and emotional outlet in our daily lives is rather obvious.

Rosanoff² writes of this most prevalent type of insanity as follows: "August Hoch finds in a large percentage of his cases of dementia praecox (51-66 per cent) evidences of a peculiar mental make-up which he has termed 'shut-in personality.' This

Rehearsal of "A Midsummer Night's Dream," showing the sleeping Titania.

recreation are first to recognize that it is the spirit even more than the actual activities which count for most.

The most effective occupational workers are without question those who recognize the value not only of constructive but also of pleasurable activities, who use their entire program as a vehicle for the expression of personal interest and wholesome contact with the patient. In their regular departmental work every avenue of approach is sought, and physical activities, directed games and plays, and socialized music, as well as the conventional types of constructive work, form a very helpful part of their program.

We have but to consider the relation of work and play with normal people to understand the validity of this conception. Our entire philosophy

2. Rosanoff: *Manual of Psychiatry*, 5th ed., J. Wiley & Son, New York, 1920.

make-up he defines as follows: 'Persons who do not have a natural tendency to be open and to get into contact with the environment, who are reticent, seclusive, who cannot adapt themselves to situations, who are hard to influence, often sensitive and stubborn, but the latter more in a passive than an active way. They show little interest in what goes on, often do not participate in the pleasures, cares, and pursuits of those about them; although often sensitive they do not let others know what their conflicts are; they do not unburden their minds, are shy, and have a tendency to live in a world of fancies. This is the shut-in personality.' And he adds further: 'What is, after all, the deterioration in dementia praecox if not the expression of the constitutional tendencies in their extreme form, a shutting out of the outside world, a deterioration of interests in the environment, a living in a world apart.'

If this is the underlying basis of even one type of mental disorder, and of that type which especially has been most responsive to occupational therapy, surely we should not need to spend much time in arguing for that attitude toward the treatment that would most effectively divorce it from monotony and drudgery.

Rosanoff says in reference to the treatment of dementia praecox, "An effort should be made to combat stereotypy in all its forms by suggestion and by diversion and occupation." We are surely then justified in suggesting that occupation should not become stereotyped.

White³ has the same attitude toward this subject:

The treatment (of dementia praecox) must be entirely symptomatic. A careful search should be made in each case for functional abnormalities and for the origin of mental conflicts and correction applied as far as possible.

Many cases will, of necessity, have to spend most of their lives in a hospital. It is therefore desirable to educate them as early as possible in good habits. They should be encouraged to some form of occupation, preferably

out of doors. Under the influence of hospital surroundings and farm life these cases may get on very comfortably and the deterioration process be considerably retarded.

It seems probable that one of the best methods of approach to the treatment of these cases would be by the method of reeducation through the agency of industrial training. If this is to be done intelligently, however, it is essential that the patient be not merely put to work in a haphazard way, but that a sufficiently careful analysis of the psychology of his particular condition be made so that it

pected that material results will be obtained. In the few cases that have been worked upon in this hospital along these lines the improvement has been prompt, marked and considerable. Such improvement is of course open to the criticism that it might have taken place any way in the natural course of the disease, and requires further and more elaborate studies to define its possibilities. The principle is to work out an adjustment in the environment that will bring it within the powers of adaptation of the patient.

If the treatment of these cases is a matter of working out an adjustment to the environment and if the whole modern movement for reeducation is not built upon a false foundation, we have but to study how play and play activities contribute to the education and personal adjustment of the normal child to realize how large and how little cultivated a field we have in the use of recreation with the insane.

The few institutions which are really taking this matter seriously are reporting very remarkable results. No claim should be made at this time for a positive curative value for recreation. Those who are working hardest and doing the most fundamental thinking on the subject of mental diseases are the least dogmatic in their statements, but all of those who have been experimenting with the recreational aspects of occupational activities report wholesome results in numerous cases. Fortunately, however, radical and astounding "cures" are not reported. There is always danger in excessive claims based upon insufficient data, especially when laymen are called in to assist in highly technical problems. The fact remains, however, that a number of careful and experienced hospital superintendents and clinical directors

have not hesitated to state to the writer that this is one of the most hopeful and interesting experiments which is being conducted in the entire field of psychiatry at the present time.

It is also worth while to call attention to the fact that in many instances there is such improvement that patients have comfortably and

Free to Grow

THE July issue of THE NATION'S HEALTH assumes a new external form more in keeping with the flexibility, interest, and vitality of the subject.

In point of editorial service THE NATION'S HEALTH has long enjoyed the privileges and responsibilities of leadership. The new form now achieved permits the utmost degree of expansion, and in external feature as well as intrinsic quality gives a just perspective of public health activities.

THE NATION'S HEALTH, now as always, serves the cause of preventive medicine by offering the health executive of the municipality, the industry, or the institution, a comprehensive account of health happenings everywhere.

Extend your individual contribution to health journalism by writing THE NATION'S HEALTH in regard to any work in your community of special merit or unusual urgency.

Let us have an expression of opinion from you on our new appearance. And tell the editor how the magazine may be made to serve you personally.

will appear what is the best method of approach to arouse his interests and fix his attention. It is also necessary to bear in mind the motor disturbances, more especially of the catatonie group, because here the education will have to be addressed more or less to restoring certain motor adjustments. The same principles are involved in treatment of this sort as have been long recognized in dealing with the mentally defective. The avenue of approach to the individual must first be worked out before it can be ex-

Home-Making Experts Confer on Cincinnati's Housing

When the Visiting Housekeepers Told Cincinnati How the Other Half Lived, Four Hundred Thousand Dollars Were Spent to Better Conditions in Tenement Homes

By BLEECKER MARQUETTE, CINCINNATI BETTER HOUSING LEAGUE, CINCINNATI, OHIO.

THE scarcity of homes that has come about as a result of war conditions in practically all our communities has tended to focus attention on the housing problem, perhaps more than ever before. Today the problem of an adequate supply of good houses at reasonable rents is one that confronts not only the poor people of the community, but those of us in moderate circumstances. In the days preceding the War when most cities had a reasonable supply of houses in excess of the demand, owners were bidding for tenants and most of us had no great difficulty in finding what we considered satisfactory accommodations at a fair rental. Today that situation has changed materially. The average citizen is in a much better position therefore to understand what it means to the poor to have to pay high rents for the poorest quarters. As a matter of fact, the poor people have to pay more in proportion for their rooms than people of moderate means.

It would take considerable space to tell the story of what Cincinnati has tried to do to improve its housing conditions. We have realized that there are many phases of the problem and have tried to approach it from as many different angles. We have realized that the real hope of eliminating bad housing conditions lies in a comprehensive city plan for safeguarding the future building development of the community. The Better Housing League has devoted much of its attention, therefore, to constructive, forward-looking measures which seek to insure that all homes built in the city in the future shall comply with reasonable requirements for good housing

and not provide potential slums. The city has a tenement house code which gives reasonable assurance that all tenement houses constructed in the future shall be so built as to comply with good housing standards.

to persuade them to buy a house. In many cases it would place upon them a burden that they are entirely unable to carry, and not infrequently it has resulted in breaking down the health of both parents and in the loss of their equity in the property. At the same time we prefer to have these families live in a rented single or two family house rather than in a rented tenement flat.

Cincinnati needs a more modern system of housing legislation which will regulate more strictly the construction and maintenance of all types of houses used for dwelling purposes instead of tenements alone. The Better Housing League, however, has postponed its efforts in this direction pending the results of the very important work now under way of formulating a city plan. A well conceived, comprehensive city plan will take care of many of the evils that develop from a lack of regulation of the construction and location of small houses. By a system of zoning which is becoming more and more popular in our American cities, city planning protects the residence district from invasion by factories

and business buildings, and other undesirable uses, so that a man may invest his lifelong savings in a home without incurring the risk of having his property value destroyed by a varnish factory built on the adjoining lot. A zoning system will also regulate the height of buildings and the portion of the lot they may occupy in such a way as to safeguard the distance between houses and prevent the development of congestion in outlying areas of the city. It has been felt that it

Sanitation for the Submerged Classes

THE average tenement dweller in any city must kick his environment out from under him if he arises from the submerged class. The combination of dirt, confusion, noisome atmosphere, and general conditions of discouragement are cause as well as effect of inadequacy.

Community as well as individual responsibility attaches. Garden City children are in every way happier and more robust than those in less favored industrial cities near by. Improving the plumbing improves the morale of a community. Sloth is the companion of discouragement.

Cincinnati visiting housekeepers in 1922 made 8,939 visits to families. They found time as well to aid 107 immigrant families and to find homes for 260 families exhausted in their efforts to find a home.

The opinion is quite generally accepted among students of housing that the tenement house is not a satisfactory place for poor families, particularly those having children. We believe in promoting the construction of the small house for one or two families. We believe that those above the submerged class should be given an opportunity so far as it is possible to own their own homes. We realize that for those who have a difficult time making ends meet it would often be an injury rather than a benefit to try

would be wiser to wait until the city plan has been developed and a zoning system worked out before attempting a complete revision of our housing regulations.

Meanwhile the League has done all in its power to keep in touch with the type of one and two-family houses constructed in the city to see that the growth is along proper lines, to encourage the development of well constructed small houses and to discourage the construction of tenements. Due partly to the efforts of the League, but probably much more to economic factors, the new tenement house has not developed to any extent in Cincinnati. During the past five years there have been so few new tenements built that they are practically a negligible quantity.

Shortage in Cincinnati

A careful investigation of the trend of home building since 1915 shows that the city has a shortage of more than four thousand houses. It is comparatively simple to estimate the shortage because of the very stable growth of Cincinnati's population. It has approximated one per cent a year for the past ten years. We know the number of houses built in a normal year and we also know how far we fell short of this number during the lean building years of the War, in one of which, for instance, there were only 106 houses built. There can be no question but that it will take some time to build enough houses to meet the demand. Despite the fact that the year 1922 was a banner year in home building, a total of nearly nineteen hundred homes having been constructed, so many dwellings were torn down to make room for industrial and business buildings that we were practically no better off at the end of 1922 than we were at the beginning of the year.

Cincinnati still has a serious problem in its existing tenement houses. Yet we may look back upon the past in comparison with the present with

some degree of satisfaction. While eight or ten years ago Cincinnati was classed among the very badly housed cities, so much has been done to eliminate the old pest spots and the more

much better than vaults, whereas today that number has been reduced to about five hundred, and orders have been issued for the removal of those remaining. Each year many dilapidated, old tenements have been condemned. They would have been condemned faster had it not been for the shortage that has accrued since 1917. During the past year the housing bureau, as a result of its orders, caused the expenditure of some \$400,000 in improvements in the existing tenement houses.

Visiting Housekeepers

The housing problem is not only one of bad structural conditions in buildings but is also a problem of maintenance on the part of tenants. One of the factors that has stood in the

way of housing betterment in every community has been the fact that frequently careless, ignorant and slothful tenants will so neglect or abuse the property they live in that the owner is discouraged from making substantial repairs. The carelessness of the few has reacted to the detriment of the many. Because of their experience with occasional bad tenants, owners have tended to oppose all efforts toward housing betterment. The Better Housing League has recognized this as a very real factor and has established a system of visiting housekeepers as the most practical

method that we know of for instructing tenants and gaining the cooperation of owners. We have six visiting housekeepers, trained women of mature age, endowed with practical common sense and experienced in home making, who are spending their entire time every day in the year going from home to home in the

most congested parts of the city, bringing pressure to bear upon negligent and slothful tenants and bringing kindly help and advice on housekeeping problems to discouraged mothers. They go into the home as advisers and friends to teach tenants how to make the best

(Continued on Page 422)

outstanding of our housing evils that we have moved forward into the rank of cities that are active in housing betterment.

The enforcement of the city's housing regulations is divided between the housing bureau of the building department, which has charge of structural conditions, and the sanitary division of the health department, which is responsible for the sanitary conditions. There has been a most excellent spirit of cooperation between these departments and the Better Housing League. The League has done all in its power to build up

This view of the hillside looking toward Rookwood Pottery, formerly a neglected waste, is now planted with vegetables and grass, due to the efforts of the Better Housing League visiting housekeeper.

support for them and to give them that constant encouragement which is necessary for city officials charged with so discouraging a task as enforcing housing legislation. The amount of work that has been done is commendable. Ten years ago, for instance, Cincinnati had thousands of old catch-basin toilets which are not

Insanitary School Surroundings Are the Rule

Author Holds That Life Span Has Increased Because Urban Populations Have Learned to Demand Sanitation

BY W. R. CONARD, CONARD & BUZBY, CONSULTANTS AND ENGINEERS, BURLINGTON, N. J.

SOMEWHERE in print the author recently saw the statement that the average span of a human life in the United States today is 56 years as against an average of thirty-five years fifty years ago. This means that if we can go on finding means of preserving the health and lengthening life in the same proportion for the next fifty years, that the average of human life in America will exceed the allotted three score years and ten. How are we to account for this, is a natural question to ask, and the answer in part (for the purpose of this short article) is to be found in the fact that within the time spoken of the majority of our population has changed from suburban to urban and that this urban population tending to spread itself over larger areas than heretofore, is demanding the most modern in the way of sanitary equipment devices and conveniences in their dwelling places.

Some few years ago, the average prominent citizen in speaking of his childhood almost always referred to the little Red School House as his first direct contact with education. Now, while practically all of us get pleasure from harking back to our childhood days, how many there are who appear to forget that with the little Red School House they were usually crowded in one large room poorly ventilated without regard to the volume of air space that should be allotted each pupil, and when nature functioned that it was necessary to go out either in the cold of winter or the heat and disagreeableness of the warmer weather. How many there are who forget that when thirst demanded satisfaction either one had to go to the water bucket in the corner with its tin dipper from which all drank or else to the yard pump often with the well in fairly close proximity to the toilets, and liable to contamination of the water from those same toilets, and without any realization on their part, and practically none on the part of either the teachers or the school trustees that childhood is the most susceptible period of human life

to intestinal troubles in their various forms.

Even today as is evidenced by the illustrations accompanying this article, there appears to be some lack of appreciation of the possibilities of

Township School outhouses about forty feet from school building. The pump is inside the school building.

trouble due to continuing the use of the old fashioned privy and the shallow well pump in the school yard.

Healthfulness is the key-stone which supports the arch of the span of human life, and without this key-stone the arch is likely to collapse; therefore our school authorities, and those who design and build school houses must become thoroughly awakened to the situation, and see to it that not only the new schools going up are equipped with the proper sanitary arrangements, but they should also get busy and arrange the older buildings with the right sanitary equipment and conveniences.

Referring to the illustrations accompanying this, they were taken at random and are typical of our Ameri-

can public school in the suburban and rural sections. These observations of conditions were made in a section in one of our eastern states, which has been settled many years, in fact in some instances the communities had been well established even before the Revolutionary War, and probably the school authorities would be highly insulted if charged with being old fashioned or behind the times, or with not having due appreciation of the value of our children, or with not endeavoring to see to it that they have everything for helping them to grow up to healthy manhood and womanhood, yet here are the conditions:

Twenty-five schools visited or observed of which twenty-one had the old fashioned pump and shallow well for water for drinking. Nineteen had within fifty feet of the pump the old fashioned privy. One had what is usually termed "city" water supplies and the old fashioned privy, and two had well constructed water supplies and indoor toilets.

What a sad commentary on intelligent men and women school authorities and the architects whom presumably they employed to design and advise with them on the at least comparatively new building, which all of those illustrated are.

Where one school is so situated that it cannot have modern sanitary conveniences there are at least forty-nine that are, and what an easy thing it is to have a deep well, tapping a water bearing stratum, and to install a pump and tank to supply water for both drinking and sanitary purposes and then provide the proper indoor closets with a small disposal plant so situated that it will carry away the sewage and dispose of it in such a way that it is neither unhealthful or offensive to the school or surrounding property.

The value of human life cannot be measured in dollars and cents, and what an asset to any community either urban, suburban or rural is a general condition of good health among its residents. Therefore how important it is that care be exercised

Township School outhouses about seventy-five feet from pump, fifty feet from new building, and fifteen feet from old building which is still being used for school purposes.

Borough School outhouses in good condition and about fifty feet from building. The pump house is close to the school building and seventy-five feet from privies.

to see that all safeguards are secured for our schools, especially with regard to the water and sanitary arrangements.

Suppose we see how much it will cost to have the right arrangements for water and sewage disposal for the country school. The school board doesn't have the money to lay out in a lump and does not want to raise it by tax all in one year, but can borrow the necessary amount and can pay it back on long time notes. To provide modern water supply, plumbing and sewage disposal will cost about ten dollars per pupil for the ordinary school. To pay this off in ten years would cost the first year \$1.60 per pupil, and this would diminish year by year until the tenth year when it would be \$1.06 per pupil, and thereafter it might cost fifty cents per year per pupil for repairs and maintenance, which is very little if any more than it costs with the crude and insanitary conditions found in many cases. Surely if viewed in the light of an insurance tax that is not much, being on an average five cents per pupil per month for the school year.

Few indeed are the schools so situated that it would be impossible to install a driven well, either shallow or deep, from which a good potable water might be obtained. In connection with the well a hot air, gasoline or kerosene driven engine and pump and in many instances an electric motor and pump together with modern plumbing and pressure tank could be installed. Few there are of these same schools that are so situated that they could not have the toilet indoors, and connected to a modern system of sewage disposal either by discharging into a cess pool, digesting tank and chamber and from there into underground drains usually known as French Drains, or else into the more modern, and better settling tank and sludge

bed with the liquids flowing away either to French drains or other similar means of filtering and disposing of the liquids.

What better piece of work could be done for our American childhood than to stage an energetic campaign to bring to the attention of the proper authorities and to urge them to take the proper correctional measures for remedying the matter and putting all of our schools throughout this broad land of ours, which are not so arranged, on a proper sanitary and health basis?

Common But Unrecognized Dangers of Furuncles

Physicians call them "furuncles"; the English elegantly call them "spots"; we Americans with a genuine love for words of simple roots call them "pimples." The Anglo-Saxon was "piplan," a blister, but the word, not illogically, became confused with the French "pimper," to spruce, and its more vulgar contraction. Whatever we may call them, these minute pustules constitute a very common type of infection, one which not only mars many a complexion but may even be the forerunner of a more serious condition. Any chronic suppurative condition no matter how small does a certain amount of physical harm. Their presence may be a sign of lowered bodily resistance contributed to by a faulty dietary and lack of thorough cleanliness. They may indicate some really serious condition, but usually they do not.

The very frequency of furunculosis and the fact that pimples usually subside when opened, has led to the dangerous custom of squeezing, pressing, pricking, or puncturing them. No inflammatory area should ever be subjected to rough manipulation. This is apt to increase the zone of infection and in situations having a rich blood-supply like the face and lips there is

always the risk that the pus-producing organisms may be thus forced into the venous circulation and carried by the blood-stream to some other point in the body there to do really serious mischief. Every wound is always followed by the deposition of scar tissue and naturally, the larger the wound and the greater the amount of tissue destroyed, the bigger will be the size of the scar. It is the tendency of all scars to contract. If they are upon the face, ugly looking blemishes may be thus produced.

It should always be the rule to treat these apparently innocent minute boils as dangerous infections. They should not be violently compressed and opened with any sharp instrument at hand regardless of its cleanliness. They should be put at rest under some bland ointment or if lying deeply in the skin, evacuation may be hastened by the application of small, hot compresses. They should not be punctured until they are "ripe" and then only with a sterile instrument and with the minimum amount of damage to the skin. Discharge of the pus should never be accomplished by strong pressure. Gentleness must characterize all these manipulations.

These are simple teachings of which the layman stands greatly in need and, since public health workers are interested in any condition which handicaps or threatens mankind, these simple precautions should be made known to the public.

The Philippine Island Social Hygiene Association has applied for a charter. The educational and religious leaders of Manila formed this organization to study and better social hygiene conditions in the islands. Activities already under way include a survey of vice conditions in Manila and of the sex educational literature used in the normal schools and colleges.

Protecting the Belgium Worker's Health

Both Industry and the State Have Taken Bold Initiatives in Health Service as the Best Means of Raising the Health Level of the People

BY DR. D. GLIBERT, DIRECTOR OF MEDICAL SERVICE OF THE MINISTRY OF LABOR, BRUSSELS, BELGIUM.

BEFORE the war, which upset nearly all of our institutions, prosperous Belgium was in possession of important medical and hygienic machinery, functioning for the special protection of its working people.

This country, as well as other industrial countries, had for a long time been endowed with a certain number of medical and allied institutions founded exclusively by the philanthropic heads of great firms. Many years ago the Belgian government took efficient steps toward the protection of the workers' health, while at the same time, working people themselves began through their unions to combat the disastrous consequences of disease. Such foresight is quite natural for a densely populated nation which has since ancient times been a field for the most intense industrial activity. In addition the geographical position of Belgium, which makes it the crossroad of Europe and a place of contact for the great neighboring nations, with which it maintains closest relations, favored Belgium in turning to its own advantage the progress made by these neighboring countries.

While Belgium was little by little improving its methods and increasing its sanitary institutions, confident in continued peace and industrial prosperity, it awoke suddenly to find itself under a foreign yoke, its industries thoroughly paralyzed and wholly ruined.

When the storm was over, although it was cruelly wounded, the Belgian nation promptly recovered its activity and, like the diligent ant whose work has been destroyed by the foot of a passer-by, it took up again its labor with patience and tenacity. It wanted not only to restore the ruins of its old

institutions, but also to improve and increase its economical and social status in order to meet the distress of its industrious citizens.

Present Trends

It is proposed to show in this note

tion, any measure they deemed useful for the protection of the workers' health. This Act, still in force, may be considered as the basis upon which the social legislation of today has been built.

Independent of this Act, an Imperial Decree, dated October 15, of that same year, 1810, constitutes the first step in regulating the establishments not subject to the Act concerning mines, but presenting some dangers for the neighborhood. This decree, concerning the "factories reputed dangerous, unhealthy or troublesome," has been revised several times. The last revision was in 1863. It has kept its legal force up to the present date, and is now being re-examined again.

It is necessary to remark that most of the more or less important industrial establishments are subject to one or the other of these regulations. It is equally necessary to add that we must come to the end of the last century to see legal measures of protection extended to all industrial and commercial establishments.

In 1886, some insurrections, some important strikes and riots took place during which we had to deplore the sacking and the

burning up of a few factories. In the presence of such serious signs of deep dissatisfaction, the Government, after conducting a great national survey on the working people's condition, took a definite step in official intervention by the promulgation of an Act regulating the employment of women and children (Act of 1889). This was our first great social law.

From then on that tendency of intervention increased till we came to the most recent Act, that of June 14, 1921, limiting the work day of the

All Cooperate in the Interest of Health

PRIVATE philanthropy, which always moves more swiftly to relieve than state or other agencies, long ago provided special medical and allied institutional aid for ailing work people in Belgium.

State medical and hygienic machinery, developing parallel with activities of the peoples themselves through workers' unions, has promoted an intensive industrial service that is well calculated to restore the level of the working people's health in this and future generations.

Sanitary service in industry includes organization in 903 industrial concerns employing 523 doctors, a part of whose service is the continuous health supervision of 23,481 young people. Moreover, health is promoted both by opportunity and necessity, for the code demands penalties from both workmen and employer for its transgression.

what the war destroyed and the results of Belgium's activity in restoring the same, as well as the aim towards which we are striving.

In 1810 when Belgium was united to France, we find legislation protecting in a certain measure, the health of special classes of working people. The Act of 1810, relating to mines and metallurgy, granted to the "mine officers" extended powers according to which they could easily impose, on the industrial enterprises within the limits of their jurisdic-

adult male to eight consecutive hours.

It is impossible to give, in such a short article, a complete resumé of all legislation concerning the protection of working people, since the present work code fills a volume of more than four hundred pages. It will be necessary, therefore, to limit the subject and merely mention some of the regulations of direct concern to the medical hygienist.

These depend largely on the application, by means of special orders, of provisions made by virtue of the Act of 1810 on mines, or the royal decree of 1863 already mentioned, or else, an Act of much larger scope (the Act of July 2, 1899) called "Safety and Health of Laborers' Act."

Thanks to these legal provisions and some particular laws, such as the Workmen's Compensation Act of December 24, 1903, and the coordinated laws on public instruction, and on child labor, the machinery for the protection of the workers' health requires the following prophylactic measures:

The age required for admission to work is actually fourteen, but permission is granted to youths of thirteen who can show a certificate of completed primary studies. This is a general rule; it applies both to girls and boys and to all industries.

In addition a great many reservations are made prohibiting the employment of young persons, said to be "law protected people" (before ages varying from fourteen to eighteen for young men, and between fourteen and twenty-one for girls) in certain work considered too hard or unwholesome for them.

Legislation goes still further; it sometimes prohibits the employment of women of any age, in certain industries such as coal mining, or allows the employment of "Law protected people" or women of any age, for night work, only under special circumstances.

Industrial Sanitation

Industrial or commercial undertakings of any kind are subject to certain hygienic regulations of which the main provisions are as follows:

Under ordinary conditions workrooms must supply to each worker a volume of air not less than ten cubic meters. Workrooms must be at least 2.50 m. in height. The air supply shall not be less than thirty cubic meters per person per hour; and, when work is especially unhealthful, this minimum is doubled.

The work and places must also be

suitably warmed and, in summer, protected against high temperatures.

Workers must have at their disposal good drinking water and the water used in the workshops either for pulverization or for sprinkling must not be polluted.

There are also more special regulations concerning other causes of unhealthiness: ejection of steam, gases, dusts; cleanliness of rooms, removal of wastes and manufactured products of objectionable kinds, lighting of rooms, etc.

As to the personal hygiene of the worker, general rules determine the number of toilets and urinals which have to be maintained; they also prescribe that, in the place where work of a particularly unhealthful character is being done, special work clothes will be furnished as well as cloak rooms and washstands.

Finally, it is forbidden to eat or bring food into work places used for the manipulation of toxic materials and the workers are also prohibited from bringing alcoholic beverages onto the company grounds.

Responsibility Mutual

An important thing to be noted regarding Belgian regulations is, that they provide punishment for the workmen as well as for the employers transgressing them.

Apart from these general measures, a series of more detailed ones are applicable to specially hazardous industries; for instance: the manufacture of lead compounds; preparation of raw materials for the hat trade; the use of white lead in earthenware factories, etc.

From a medical point of view, aside from prescribed sanitary measures, these special regulations order periodical clinical examinations of the personnel either each year, each half, or each quarter of a year. These examinations are now made by medical officers of the State.

In the same way, special sanitary regulations provide for protection against certain infectious or parasitic diseases: compulsory disinfection of horse hair used in the making of brushes or mattresses; vaccination and periodical revaccination of people handling rags; examination of miners exposed of ankylostomiasis, etc.

Among the other special laws, protecting the working people's health, should be mentioned, besides the prohibition of work to women during the four weeks following delivery, the Act ratifying the Convention of Berne (September, 1906) which forbids the

employment of women of any age at night work.

As to the compensation for injury from industrial accidents, the plan of the present law is as follows:

What is required, is not compulsory insurance, but compulsory compensation. At a matter of fact, nearly all the manufacturers are insured. Those who are not, have to bear personally the consequences of accidents occurring on their premises; moreover, they contribute, by paying a special tax, to the up-keep of a state "Guaranty Fund" which is intended to serve to indemnify the victims in case the employer, who is not insured, is insolvent. Only contracts with societies approved by the State, are considered valid, and, to be officially approved certain conditions of solvency must be realized and these conditions are subject to a permanent control. Hence it is seen that the injured workman is always certain to obtain his compensation.

The idea of the lump-indemnity has also been adopted, i. e., nobody has to take into account the question of personal responsibility; and in consequence, the workman receives his compensation even when there has been serious carelessness on his part. Neither does the preceding state of health of the victim enter into account, so that a one-eyed man who accidentally lost the sight of his good eye, would receive an indemnity for total blindness, just as if he had really lost, by accident, the sight of both eyes. On the other hand, the compensation is not complete, it amounts to only fifty per cent of the loss suffered.

The cost of treatment is paid by the employer, who can choose one of these two methods: he may either organize a medical service or have it organized by an insurance company which acts in his place; in which case, the workman is not free to choose his doctor, or if the employer does not adopt this method, the injured worker is allowed to choose the surgeon he prefers, but a royal decree fixes the maximum rate of the expense to which the employer is liable.

New Legal Provisions

All the above was existing long before the war and has again been enforced since the evacuation of the country by the enemy. But, since that time, important improvements have been made in certain of our social laws. The principal new provisions are the following:

(1) A law has been promulgated limiting the work day of adults to a

Opium and Its Control Through the League of Nations*

The Representations of the Advisory Commission in Traffic on Opium Embody the General Principles for the Control of Dangerous Drugs

By GERTRUDE SEYMOUR, NEW YORK CITY.

IT IS a wise officer who knows whether a consignment marked "Lamps" is really lamps or several hundred pounds of morphine; whether a package labeled "Cocoa Powder" contains the wherewithal for that grateful and comforting beverage or only "dope." And when is a registered letter only that, and nothing more? When does it hide its fraction of the six hundred pounds or more constituting the year's output of one astute firm? Perhaps one should say, the former output, thanks to agencies and methods here to be described.

All this is not mere allusion to catchy news items, but to historical facts, actual events in the recent development of a business-like control of traffic in opium and other narcotic drugs. This has been recognized as an international problem for nearly a quarter of a century. The pioneer meeting in Shanghai, 1909, drew together nations which had been engaged in efforts more or less successful within their own territories to restrict drug trade to its legitimate sphere. Their recognition of interdependence in this matter expressed by the Shanghai meeting broadened into a definite agreement on the subject at the three Hague Opium Conferences of 1912, 1913, and 1914; and the first International Opium Convention assured to measures for narcotic drug control the status of an international obligation.

Then the war. And after war the

peace treaties, each providing that ratification of the International Opium Convention should be implied with the ratification of the treaty itself. And the new League of Nations, whose members agreed to intrust to

lands Government to the Council of the League of Nations, prepared in 1920 by M. Van Swinderen, Netherlands Minister to London, and, it will be recalled, the presiding officer of the Shanghai meeting, as well as tactful

guide in questions of control of opium on other occasions. M. Van Swinderen naturally took the initiative in bringing the opium question to the Agenda of the First Assembly, since the Hague Convention had committed to the Netherlands certain responsibilities connected with its enforcement. With this government ratifications of the convention were to be deposited; official communications between signatory states regarding opium should go through the medium of the Netherlands government; should disputes arise in course of any enforcement of the convention, this government should be the mediator, with authority to call a special conference at The Hague if the matter could not otherwise be adjusted. The memorandum reviews also the new alignment of states resulting from the new agreements. Between the year 1912 and 1914, forty-two states had signed the International Opium Convention, but only nineteen had ratified it. The protocol of 1914—permitting enforcement by any signatory nation at once

without awaiting final ratification of the convention—had been accepted by only six nations, when war postponed further activity in this field. But now, instead of the simple classification of signatories or non-signatories, four groups of states must be considered: (1) States, members of the League of Nations, adherents to the Opium Convention either by their own earlier ratification or by the ratification of

Opium Trade a Profitable Occupation

DRUG addiction as a hold-over from acute disease conditions that require anodynes is the least part of the problem. Its enormous extent is rather the logical outcome of the promotion of a highly profitable trade which will flourish at the expense of public health, stability, and morals as long as it continues to pay upscrupulous dealers the coveted profit.

The agreement reached at the recent session of the Opium Advisory Commission of the League of Nations proposes negotiations between the countries in which morphin, heroin, and cocaine and their respective salts are manufactured, and those in which raw opium and coca leaf are produced.

The world is now charted as to sources of raw materials, channels of exchange, and points of reshipment and manufacture. Control henceforth depends upon properly coordinated international effort.

its supervision the traffic in opium "and other dangerous drugs, subject to and in accordance with the provisions of international conventions existing or hereafter to be agreed upon."

The gap between the old procedure and the new is bridged by a document of permanent significance in the history of the control of opium. This is a memorandum from the Nether-

*The sources of information utilized in this article are exclusively the publications of the League of Nations: Official Journal, Records of Assembly meetings, minutes of committee meetings, received through the courtesy of Dame Rachel Crowley; and special notes from the Information Section, by the courtesy of Mr. Arthur Sweetser.

one of the peace treaties. (2) States signatory to the Opium Convention but not yet members of the League; (3) Three states, members of the League, who have not yet signed the actual instrument of the convention, and (4) six states standing outside of both Convention and League.

Affirming a belief that in these changed circumstances the Secretariat of the League of Nations was the "most suitable center for all international action," the Netherlands government urged that at the coming assembly the opium question should be fully considered by a committee representing all nations most concerned, and a plan of work formulated by which the League might best carry out the provisions of the International Opium Convention. The Netherlands itself stood ready to cooperate in any way with the League.

Then in the First Assembly of the League of Nations, December, 1920, deliberations on the Memorandum both in the "Fifth Committee" and in full Assembly, led to the adoption of a resolution covering the following points:

The Secretariat shall collect information as to arrangements in different countries for carrying out the provision of the International Opium Convention, and as to production, distribution and consumption.

An Advisory Committee shall be appointed representing the countries most affected by the opium problem, and reporting annually on the observance of the Convention.

The Netherlands government shall invite the adherence of states not yet signatory to the Opium Convention.

In the discussions at this First Assembly the most radical note was sounded by the Chinese delegate, who urged that control of opium should reach beyond distribution or even manufacture, and should strike at actual cultivation of poppy plants. He was not unaware that during the distractions of war, foreign and at home, there had revived in China cultivation of the forbidden plant. But he indicated the special measures even now being taken to check the recrudescence and believed the situation only temporary. China had sacrificed more than one hundred million francs of revenue from cultivation of the poppy, had bought and publicly burned ten million dollars worth of smuggled opium; she would not now fail in her undertaking. Public opinion was strong against opium in the younger generation. China's main problem was the existing system of foreign concessions and consular services, it was gently but definitely indicated. A remarkable spirit of frankness and

conciliation pervaded the discussions. England was aware of excessive amounts shipped to the Far East and had called attention of her Foreign Office to the matter. Japan offered to investigate strictly the contraband trade in morphin centering in her country. And willing cooperation to attain better conditions brought the request from Portugal for membership on the new committee soon to be formed, and Siam welcomed this acceleration of efforts in the practical control of opium which she had already attempted. There was not an opposing word; only recognition anew

Underwood & Underwood
An automobile accidentally bumped into a barrel of "fish" recently which was just being unloaded at a New York pier and the crash revealed a sealed tin container, stuffed with morphin. The entire consignment was found on examination to contain illicit narcotic drugs valued at three-fourths of a million dollars. The picture shows a customs inspector with \$750,000 worth of drugs.

of the grave situation affecting equally nations of East and of West.

The new Advisory Committee on Opium was created at the meeting of the League Council in February, 1921. Recalling instructions of the first assembly that this Committee should include representatives of all countries most affected by the problem, the following nations were invited to make appointments to its membership: Great Britain, France, India, China, Japan, Netherlands, Portugal, and Siam. Later, a representative from Germany was included. Still later an unofficial observer came from the United States.

As the personnel of this Committee has changed but slightly, the list of January, 1923, is given here. At first, China was represented by Mr. Wellington Koo. The American representative sat first with the Committee at its January session. The Serb-

Croat-Slovene State, although invited to send a representative to this Committee, has not yet done so.

Government Representatives are as follows: Sir Malcolm Delevingne, British Empire; Mr. Chao Hsin-Chu, China; M. Kahn (substitute, M. Bourgeois), France; Dr. Anselmino, Germany; Mr. J. Campbell, India; His Excellency, Mr. A. Ariyoshi, Japan; Mr. van Wetsum, Netherlands; His Excellency Mr. Ferreira, Portugal; His Excellency Prince Charoon, Siam, and Dr. Rupert Blue, U. S. A.

Assessors are: M. Henri Brenier, France; Sir John Jordon, Britain, and Mrs. Hamilton Wright, America. Dame Rachel Crowley is secretary. The Opium Section at first created in the Secretariat to deal with the mass of headquarters work, was last year merged with the existing Social Section.

This Advisory Committee on the Traffic in Opium and other Dangerous Drugs—to use its full title—has held four meetings. No attempt is made here to trace the chronological development of its work in detail from the first gathering in of available information regarding arrangements by signatory nations for executing the Opium Convention, to the administrative plan now approaching completion and to be submitted to the Fourth Assembly, in September of this year. But certain facts in the development of this plan demand special mention: The questionnaire; two special inquiries into legitimate requirements of drugs mentioned in the convention and of others of similar effect and into legitimate requirements of raw opium; the certificate system; and ever and always, the call to adherence to the Opium Convention, for the success of any plan of control depends upon its adoption by all nations.

This document is in five sections, following the chapters of the convention of 1912 on raw opium; prepared opium; medicinal opium, morphin and cocaine; relations with China; and other information. Copies of laws and regulations as well as a summary of these, statistics of amounts grown, manufactured, and distributed, accounts of administrative method, how smuggling is controlled, and similar facts, are asked in each section; and the final section inquires whether the study of Indian hemp, recommended by the convention, has yet been made and, if so, with what results, and how far the provisions of the Convention are applied to coca leaves, ecgonin, and the derivatives of drugs definitely specified, to the alkaloids of opium, or

to other substances "liable to similar abuse and productive of like ill effects."

The Summary of replies to this questionnaire, issued in June, 1922, is a startling document. For the first time there are assembled authoritative official data regarding the extent of the problem, and official statements as to what is—and what is not—being done to meet it. The tabulations cover first, the production of raw opium; second, imports and exports of raw opium; consumption, manufacture, and export of prepared opium; of medicinal opium; morphin, and derivatives; and of cocaine. That these returns as a whole were inadequate as a basis for action was inevitable. Because of war conditions, legislation was too recent actually to have proved its effectiveness. Few countries had any provisions for statistical records of manufacture, import, export, or distribution of the drugs in question, or any others. But the significance of the document is, for the interested reader, its revelation of the stupendous magnitude of the task undertaken, and its complexity. There are bald figures indicating the acreage under poppy cultivation—Japan's 929 acres; Serbia's 5,000 to 8,000 hectares, or 15,000 to 20,000 acres; India's 143,000 acres in 1920 for the 363,000 acres of a decade ago. No reply came from Turkey nor from Persia in time for printing; Turkey's pre-war export averaged about 432,000 kilos, or over 950,000 pounds. An increased production in China is attributed to the disturbed condition of the country, military demands, and smuggled opium and morphin from foreign countries into China. New sources of supply seem possible in Austria and Hungary. New trade is evident as, for instance, that recorded in exports from the United States to Formosa, amounting to over 12,000 kilos in 1919, and to 90,000 kilos in 1920.

Further—if the Summary startles by its revelation of the greatness of the task, it also reassures by its indications of active determination and honest cooperation on the part of many nations. Despite the distractions of the five years following the Opium Convention, nations signatory have not been neglectful of their ob-

erving special points of inquiry, and taking the first step in actual administrative control. These recommendations were after consideration approved by the Council, and are here given with their serial numbers since in documents they are frequently referred to as the "third recommendation," or the "seventh." The recom-

mendations of 1921 follow:

(1) That members of the League sign and ratify the opium convention as promptly as possible if they have not already done so.

(2) That the Netherlands Government continue its work of securing ratification by States not members of the League.

(3) That the Health Committee of the League or a similar organization be asked to undertake an inquiry to determine the average requirements of the drugs specified in Chapter III of the International Opium Convention for medical and other legitimate purposes in different countries.

(4) That a system of import certificates be adopted by all parties to the Convention. The procedure involved would be as follows:

"Every application for the export to an importer of a supply of any of the substances to which the Convention applies, shall be accompanied by a certificate from the Government of the importing country that the import of the consignment in question is approved by that Government and is required for legitimate purposes.

In the case of drugs to which Chapter III of the Convention applies, the certificate shall state specifically that they are required solely for medical or scientific purposes."

(5) That effective steps be taken to prevent contraband trade with China. (Recommendation 6 was postponed.)

(7) That the Committee be authorized to consider the possibility of an inquiry into the average requirements of raw and prepared opium (specified in Chapters I and II of the Convention) for medicinal and scientific purposes in different countries. The motive for this recommendation was the "world wide interest in the attitude of the League and the general desire to reduce and restrict the production of opium to strictly medicinal and scientific purposes."

Wide World Photo.

ligations. Norway's new drug laws date from 1913; Denmark's, from 1914. In 1916 France supplemented the older laws of 1845 and 1896 by a new decree. Belgium's law bears the date of October 24, 1919. Italy, aroused by the marked increase of illicit traffic in opium, passed new regulations in 1920, also Latvia. And Great Britain's Dangerous Drugs Act carries this date, a revision of all earlier legislation, in uniformity as far as possible with all parts of the Empire. Austria, Germany, Japan, Siam, date new laws in 1921. And in many cases it is specified that provision is made for record keeping that in the future will make available such statistics as were asked for now, but could not be supplied.

Two Special Inquiries

Since it was evident that replies to the questionnaire could not reach the Secretariat in time to be tabulated for the Second Assembly, 1921, the committee decided to offer as its annual report, several recommendations cov-

Philadelphia's Nutrition Work With Tuberculous Children

Camp Happy at Torresdale Pools Voluntary and Municipal Resources in Child Care. Children Under Weight But Otherwise Well Are Given a Chance to Come Back

By ELIZABETH CRISWELL, HEALTH COUNCIL AND TUBERCULOSIS COMMITTEE, PHILADELPHIA, PA.

CAMP HAPPY at Torresdale, just at the edge of Philadelphia, is a proof of what can be accomplished by pooling the resources of a volunteer agency and those of a municipality. When the Philadelphia Health Council and Tuberculosis Committee started the nutrition work for the underweight children in the spring of 1920, the need of a country place where the child could be under direct control of expert supervision was apparent. A number of children failed to make adequate gains in weight even though they were "free to gain." The discouraging fact was that lack of home control, faulty food, and bad habits were retarding the physical growth of the child.

There was little money in the treasury of the Health Council, but this did not daunt the intrepid fighters for the health of the children. An unused building was found at Brown's Farms, a part of the city property. This building had been the coach house when the Alexander Brown estate was the show place of Philadelphia society in 1880. The city, however, had remodeled the building and had used it for a dormitory for indigents for a short time so it was equipped with bathing facilities, toilets, and a large sun parlor. The department of welfare of the city was approached and interested in the problem, and the use of this building was offered to the Health Council free of charge. Further cooperation was given by the city supplying the

food already cooked from a kitchen which prepared the food for the other occupants of the estate—foundling children and indigents who farmed the grounds. The Health Council agreed to share the cost of the food; and to provide the personnel for conducting the camp.

In this improvised vacation home 161 children spent six weeks and all

mess hall—one side being reserved for girls and the other side for boys—commodious bath houses and toilets were erected. The water was supplied from a city main. A porch at the end of each bath house is provided with a line of faucets—an arrangement that sped up the tooth-brush drill in the morning.

A ten-acre garden, taken care of by the indigents, supplies fresh vegetables in abundance.

The children admitted to Camp Happy are 10 per cent or more underweight but are well children. Here they are given a chance to attain average weight under the most favorable conditions. The camp opens the first of July and closes the Saturday before Labor Day; and many of the children have the opportunity of spending

the entire summer in the open air.

The camp is operated under four divisions: (1) Administrative, consisting of supervisor, assistant supervisor, recreation supervisor and office staff; medical, comprised of resident physician, day nurse, and night nurse; counselors as follows, Captain of Boys' Counselors, Captain of Girls' Counselors, Captain of Colored Counselors, Twenty counselors—four of them colored; and commissary department including steward, chef, assistant chef, scullery man and maids.

The counselors are for the most part college men and women who are working on a volunteer basis. The supervisor of the camp is a trained nutrition worker and the physician is

Camp Happy is a tent colony covering twenty-five acres and accommodating five hundred children daily. Here underweight children, and those predisposed to tuberculosis, are afforded ideal conditions under which to overcome their handicap.

returned to the city in September, 1920, better equipped to fight the diseases of winter.

This was the beginning of Camp Happy which has now grown to a tent colony covering twenty-five acres with accommodations for five hundred children daily. Mr. Ernest L. Tustin, then director of the department of public welfare, was much interested in the general improvement in the health of the children even under unfavorable conditions and offered the Health Council the use of an open space just across the road from the building which was first used. The city built a large mess hall with a well equipped kitchen attached. In the large open space on each side of the

Abundant opportunity for play, some occupational therapy interspersed with rest, with reading and story telling make the summer at Camp Happy ideal for the children.

especially trained in children's work. In the nutrition work a large number of colored children were found to be underweight and the benefits of the camp are offered to them also. The colored counselors are in charge of a colored woman, who is a trained nurse and social worker.

The daily schedule follows nutritional principles:

a. m.	
7:00	Rising bell.
7:30	Showers and dressing.
8:00	Breakfast.
9:00	Tent inspection.
9:30 10:30	Directed play.
10:30	Lunch—milk.
11:00-12:00	Rest.
p. m.	
12:00	Dinner.
1:00-3:00	Play.
3:00	Lunch—milk.
3:30-4:30	Rest.
4:30-5:30	Occupational work.
5:30	Supper.
6:30-8:00	Play, story telling, moving pictures, dramatics.
8:00	Preparation for retiring.
8:30	Taps.

The schedule relative to play is more or less elastic as twice a week swimming in the Delaware river is substituted either in the forenoon or in the afternoon according to tidal conditions. Generous and interested citizens occasionally provide treats in the way of moving pictures and automobile rides. Rainy days require adjustment to include occupational work, reading and story telling. But rest and milk drinking, the nutritional factors so essential to physical growth, are never eliminated.

A complete record is kept of the child's physical life while at camp. Each child is weighed on his entrance and weekly weighing keeps an accurate check on the rate of gain. No

child is admitted without a complete physical examination and all correctable physical defects must be taken care of before entrance.

During the summer of 1922, 867 children spent the greater part of the summer in Camp Happy and gained a total of 1,724.5 pounds. One boy took back twelve good health pounds as additional equipment for the fight of life.

The Essential Qualifications of Public School Nurse

The school nurse, says the U. S. Public Health Service, should have good health, sound ancestry, tactful and equable temperament, and love for and understanding of children. In addition to her regular training and health work she should have some experience in public health nursing, in the essentials of nutrition, and in school sanitation. If she also possesses some knowledge of matters that seem more properly to belong to the work of the school physician, so much the better.

In general, one nurse should be assigned to from 1,000 to 2,000 pupils. If public health and school work can be combined the quota assigned to one nurse might be reduced to 500.

The "routine" duties of each school nurse, whether working with a full time or a half time health officer, comprise (1) A daily meeting, preferably in the morning, in a room set aside for the purpose, for the inspection, instruction, and disposition of all children referred to her who are sus-

pected to be suffering from communicable diseases, from parasitic skin infections, or from any complaint calling for emergency help; (2) frequent inspections of class rooms for discovering unreported cases of communicable diseases, and for noting the cleanliness, temperature, ventilation, and illumination of rooms and the seating of the pupils; (3) giving health instruction to pupils and to teachers; (4) doing follow-up work; and (5) observing the sanitary condition of the school buildings and grounds.

Where whole-time physicians are employed the work of the nurse is commonly confined to assist them; where volunteer or half-time physicians are employed her work may include much wider duties, which are of course done under the physician's direction. In rural districts, where the demand for health work is much greater than the supply, the nurse will often be called upon to act as representative of the State health officer in the control of communicable diseases and in giving instruction on posture, nutrition and general health.

On taking charge, a nurse should (1) make contact with the county and local health officers and endeavor to correlate her duties with the other health activities of the district; (2) learn the prevailing state laws in regard to communicable diseases and medical inspection; (3) establish friendly relations with influential persons and organizations interested in the work.

After making a preliminary survey to ascertain the location and accessibility of her schools, the number of pupils, the cooperation to be expected from teachers, etc., the nurse should prepare a schedule for her visits to the different schools, so that the day and hour of her coming will always be known in advance to teachers, parents, and pupils. Such a schedule will be of very great help to her in discharging her arduous duties. More detailed information on the subject is contained in Reprint No. 783 of the U. S. Public Health Service.

Dr. Frederick F. Russell, formerly director of the International Health Board's public health laboratory service, has been appointed general director of the International Health Board to succeed Wickliffe Rose, who resigned to accept the presidency of the newly incorporated International Education Board and the General Education Board.

Health in the Hills of West Virginia

The Four-H Camps of West Virginia Stand for Inspiration and Leadership Throughout the State

BY ELLIS S. TISDALE, CHARLESTON, W. VA., AND JAMES A. TOBEY, NEW YORK CITY.

THE bugle is calling again at Jackson's Mill. Its reveille summons a laughing, shouting army and the sunrise sees the rhythmic motion of two hundred supple forms. In ten minutes, the setting up exercises are over and the boyhood home of Stonewall Jackson rings with the happy voices of many children. With the dawn has come another golden day in the hills of West Virginia. Could the grim old soldier return to the fields where he played as a boy, he would gladly yield possession. For the old

West Virginia calls these camping units, which exist in nearly all of her fifty-five counties, the 4-H camps. The four h's stand for Head, Heart, Hand, and Health, the most wonderful quartet in the world, which signifies all-around development. During the summer months thousands of boys and girls in the Panhandle state get together in these 4-H camps. The movement started in 1914 and is an outgrowth of the whole farm boy and girl club program of the agricultural authorities. Needless to say every boy and girl looks forward all year to that wonderful week in the Alleghenies, at Salt Sulphur Springs, at Webster Springs or on the picturesque Elk River. Here, amid the magnificent scenery of the hill country, the future citizens of the state learn, by means of play, instruction, inspiration and health, how to become community leaders.

The sanitary supervision of all the camps in the state is under the jurisdiction of the Division of Sanitary Engineering of the West Virginia State Department of Health, of which one of the authors (Tisdale) is director. The four principal duties of the division at the camps are: (1) To ob-

tain a safe water supply; (2) to provide for proper disposal of wastes; (3) to carry on physical examinations of the children; and (4) to give instruction in hygiene and sanitation to the campers. The opportunity to inculcate in these children a knowledge of sanitary science is a most valuable one for many of them have come from the rural districts where education in hygienic principles is not always possible, is rare, in fact. In order to supervise the health work in the camps, the staff of the Division of

to the state laboratory for bacteriological examination before the camp is used. In many cases, the water proves safe, especially if taken from a driven well. Where contamination is found, chlorination is employed to disinfect the water. The children in the camps are taught where to locate wells and springs, the dangers from an unprotected supply, how to protect them, and simple methods of water purification.

Let us see how the full-time camp health director goes about the problem of getting a safe drinking water supply in a camp where he happens to find an unsafe spring or well at the time when he examines the quality of the drinking water. His instructions call for a fifty gallon water barrel to be erected upon a suitable support, about three feet in height. A tight cover is provided and a hole one inch in diameter drilled in the side of the barrel four inches from the bottom. In this hole a wooden spigot is tightly fitted. After the barrel is filled with water, one-half a teaspoonful of hypochlorite of lime, mixed with a small amount of water until a paste has been obtained, is dissolved in the barrel and good distribution obtained by stirring with a clean rod. Thus, the entire fifty gallons of water is effectually disinfected.

Some means must be provided to see that exactly enough hypochlorite of lime is added. If too much is used the water may have a disagreeable taste, so that the children will object to it and go elsewhere for their drinking water. Disinfecting an army camp water supply is an entirely different proposition from treating a summer camp water supply. Soldiers must do as their officers order them, but children from twelve to eighteen years of age will not always follow suggestions and it is therefore wise not to over-chlorinate the water. To make sure,

The old homestead of Stonewall Jackson is a thirty-five acre camp where the pick of ten thousand members of boys' and girls' agricultural clubs assemble each year for ten days of intensive development along lines of Four-H ideals and principles.

Sanitary Engineering is increased by the addition of a full-time inspector for the months of June, July, and August. He is generally a medical student employed for this purpose, who has been given thorough instruction in camp sanitation. This inspector spends his time at various camps installing water purification devices, constructing sewage disposal plants, assisting in physical examinations, and delivering lectures and holding demonstrations in hygiene.

The water supplies in the camps are derived from a variety of sources. Some come from mountain springs, others from dug or driven wells, while still others are taken from rivers. As is well known, the typhoid bacillus may lurk in the most innocent appearing of sylvan streams. In every instance, samples of the water supply of the camp are taken and sent

The boys and girls at the camp had great fun and acquired real information in making themselves the concrete blocks and fashioning out of them the spring house shown in this picture.

Learning one of life's best lessons on the playground—Co-operation. Well trained in competitive sports, close competition heightens the interest in camp.

then, that no taste will be imparted to the water, a color testing kit for excess chlorin has been devised by the Sanitary Engineering Division. After the water has been treated with the specified amount of hypochlorite of lime, fifty cubic centimeters of it are poured into a long, thin glass tube and one cubic centimeter of testing solution, added to it. If the disinfection treatment is just right, a greenish hue will develop in the tube in five minutes. A second long glass tube which has the standard green color in it is used for comparison. If the greenish hue is too light, more hypochlorite should be added to the barrel containing the water, and if it is too deep, more water can be added to the barrel to reduce the treatment. By this simple color test, accurate treatment can be carried out and the disinfection process properly controlled.

For the disposal of body wastes, several methods are used. Latrine boxes are, in most instances, constructed according to approved design. In one or two of the camps, modern flush toilets in hotels are available. Garbage is generally disposed of by burial. The children are instructed in the dangers from fecal contamination and in as many instances as possible, the boys themselves construct the latrines and so learn by actual practice what to do and how to do it. The camp director believes firmly that the best way to teach is by actually doing. A type of latrine box which may be constructed from a good board 18 feet long by 12 cuts of the saw, and twenty minutes work with a hammer and a handful of nails has been devised.

The latrine box is made four feet long, twelve to eighteen inches wide and twelve to eighteen inches high, depending on the width of the board.

After the box has been nailed together with one side open, the top, that is, the side opposite the open one, is sawed into in such a manner that two triangular holes are cut with the point of the triangle to the front, two to three inches back from the edge of the latrine box. The sharp edges may be whittled smooth with a jack knife. Over the holes thus cut, two covers are placed, attached to the back of the box by leather strips serving as hinges. The covers are kept closed when the latrine is not in use by a backstop and block so that they can not be raised to a perpendicular position and will always fall shut when not held up. A pit is then dug from

cautions there were no cases of typhoid fever at any of the camps during 1921 and 1922. The physical examinations reveal many other defects, however. Of 481 children who were examined in nine counties in 1921, 93.3 per cent were found to have one or more physical imperfections. Nearly 70 per cent had defective teeth, and about 50 per cent had enlarged tonsils. Almost a third had faulty vision, 18 per cent were under weight, 17.7 per cent had defective hearing, and 16.6 per cent had flat feet. These statistics bring out vividly the necessity for such physical examinations and for positive health instruction.

Can't see many standing around waiting for a second invitation to get in on the game, can you?

three to six feet deep and over it the newly constructed latrine box placed and the earth tightly packed around the edges of the box. Thus, the whole affair is made absolutely fly-tight. Care is taken in the location of the latrine and it is placed at a lower elevation than, and at a safe distance from, the source of water supply and the mess tent. The insanitary, disease producing, open back privy, so common in the country is not allowed at any 4-H camp. The children are thus given an object lesson at camp which will bear fruit when they again return to their homes.

As a result of these sanitary pre-

parative part of the week in camp. Lectures on the romance of keeping well, on human engineering, and the high road to health are delivered, together with demonstrations when practicable.

A day's routine in one of these camps illustrates the way in which the four H's are cared for. At 6:45 a.m. the bugle calls. In a few moments ghostly forms appear running swiftly through the morning mists to the parade ground. For ten minutes, in the light of the rising sun, vigorous setting up exercises are led by the athletic instructor. Breakfast, simple but

Relation of Safety Museum to the State Industries

By JOHN ROACH, DEPUTY COMMISSIONER OF LABOR, IN CHARGE OF ACTIVITIES OF INDUSTRIAL SAFETY MUSEUM, JERSEY CITY, N. J.

DURING the last decade a complete change has taken place in the working policy in modern industrial plants for the unsatisfactory spirit of command has given place to the more enlightened spirit of cooperation; thus spurring the worker to his greatest effort by means of persuasion, rather than demanding it through fear or force. Many of the larger and better managed industrial corporations of our country became dissatisfied with working results, a dozen years ago, and after an investigation of the possible cause of discontent and friction prevailing among their laboring forces they arrived at the conclusion that the constant migration of labor was due in a large measure to unsatisfactory working surroundings affecting either the safety, health, or comfort of their employees.

A labor policy that is not broad enough to comprehend the physical needs of the human body and its dependence on warmth, cleanliness, and nourishment must fail. Furthermore, if the labor policy fails to inspire confidence on the part of the worker that his employment is surrounded with the largest measure of safety to life and limb that its character will permit, it is entirely unsuccessful. The physical care of the worker should not be a subject for speculation or experiment. In many plants it is ranked as a matter of fundamental importance, and is placed in the same business column with the question of wages, hours of labor, and plant production.

Costly alterations and plant equipment that add to the comfort of the worker and to his safety have proved to be successful investments, because they stabilize the working force, and the improvement so effected in excellence and quantity of production lead to eventual repayment. In addition,

while the subject may be considered from the viewpoint of production and labor conservation, it must be remembered that public interest is also involved and this third factor is one of first magnitude, one before which all other interests must yield.

The maimed worker is a poor social asset and a distinct economic loss to the community. If he is injured, compensation may be paid to him or his dependents, but let us not forget that the burden of support that is provided by compensation rests upon the public as a whole.

Tremendous strides have been made in the industrial world in the work of providing safe premises for the working man, and to surround his employment with every comfort consistent with the character of the work to be performed.

The New Jersey Plant

In New Jersey the organic law gives the Department of Labor the

dustrial engineers and technical experts who are employed in and familiar with the industries of our state, so that the working codes represent practical working methods based on experience, and by reason of that fact, become in a large measure automatically enforceable.

In 1912 the Department of Labor of the state of New Jersey undertook the work of preparing safety codes covering the following industrial subjects: Fire protection, fire escapes, fireproofing, fire-alarm signals, fire drills, transmission machinery, freight elevators, engine stops, steam boilers, removal of industrial dusts, noxious fumes, and excessive heat, sanitation (including construction of toilet, wash room, and dressing room equipment), paint grinders, lead corrodors, lead oxidizers, nitro and amido compounds, hat felting, power laundries abrasive wheels, and safe practices covering the use of shellacs, enamels, and japans.

While these codes were being prepared, the department became convinced that the successful enforcement of industrial rules was dependent in a large measure on the cooperation that might be secured from employers of the labor affected by them. As these standards were the result of conferences in which engineers representing the varied industries of our State participated, there was reason to assume that employers generally were as much interested in their reasonable enforcement as the authorities who prepared them. After giving careful consideration to

the method of securing this greatly desired cooperation from the employers, the plan was adopted of asking each one of the manufacturing concerns in the state to delegate an employee (preferably an engineer, foreman, or superintendent in the plant, but in any case some employee

View of Sanitary Division, toilet and lavatory equipment, and a sanitary drinking fountain.

authority to provide safe working premises for those who are employed in factories, mines, and mills, and, in carrying out the intent of this legislation, a large number of industrial codes containing rules governing working practices have been issued. These codes are the joint effort of in-

occupying a position of trust and responsibility) to represent the department of labor in the plant, and to confer with the district factory inspector concerning an interpretation of these rules and their enforcement in that particular plant. This suggestion from the department met with a generous response from the employers, and in a short time about two thousand and six hundred representatives, or factory chiefs, as they were designated, had been appointed by the employers for this purpose.

Shortly after the inauguration of this movement, a meeting of nearly two thousand factory chiefs was held in Newark. Motion pictures were shown, various types of safety apparatus were on exhibition, excellent addresses on safety were made by competent speakers, and, in general, a great deal of enthusiasm on the subject of the promotion of safety was shown by the audience.

The need for the establishment of an industrial safety educational center became apparent to the Department of Labor about this time and the idea of such an institution became a part of the fixed policy of those who were entrusted with the responsibility of safeguarding the life, limb and health of the industrial workers of our state.

In 1910, Commissioner of Labor Lewis T. Bryant visited England, France, Germany, Austria, and Italy, to study industrial conditions and ascertain what administrative methods were in vogue in Departments of Labor in those countries. He visited the Safety Museums in Berlin, Vienna, Munich, and Milan and was greatly impressed with the educational opportunities afforded by museums of this character. On his return to America in his annual report to the state legislature, he recommended the establishment of an industrial safety museum. The legislature, however, took no action in the matter.

In March, 1919, Commissioner of Labor Bryant called a meeting of a number of the insurance carriers and other interested parties at Department of Labor Building, 571 Jersey Avenue, Jersey City, for the purpose of discussing the advisability of at-

tempting to establish an industrial safety museum.

This meeting was attended by representatives of the New Jersey State Department of Labor, Schedule Rating Bureau of Newark, and about a dozen insurance carriers, who agreed to help to finance the establishment of an industrial museum, and for this purpose about \$3,000 was raised.

It was decided to use the building under lease by the Department of Labor of New Jersey, located at 571 Jersey avenue, Jersey City. This build-

ing is a four-story building, 97 feet long by 50 feet wide. The work of organizing and developing the museum has been accomplished largely by the following persons:

Hospital Division. The equipment in this division has been standardized by the Medical Committee.

Lewis T. Bryant, commissioner of labor; John Roach, deputy commissioner of labor; C. H. Weeks, deputy commissioner of labor; Rowland H. Leveridge, chief, Bureau Electrical and Mechanical Equipment; Miss Lillian Erskine, chief, Bureau of Research and Statistics; Joseph F. Scott, chairman, Steam Boiler Operators' Bureau; and Robert Woodhouse, chief engineer, Manufacturers Liability Insurance Company.

An additional reason for the establishment of this museum lay in the fact that the passage of the Workmen's Compensation Law, in the year of 1910, compelled the reporting of all industrial accidents and for the first time in the history of the state, our citizens became apprised of the enormous physical toll that was taken annually by our industries. The ex-

losses more than 10 days work. Last year 285 of these accidents were fatal. The insurance carriers collected approximately \$4,500,000 in premiums and paid \$2,375,000 in compensation claims.

What the Department of Labor is endeavoring to do through the Industrial Safety Museum is to reduce the element of danger in our industries to the minimum. Analysis of the accidents occurring each year shows that from 75 per cent to 85 per cent are due to careless practices, while no more than 15 per cent to 25 per cent are due to causes that could have been avoided

by the installation of mechanical safeguards or other conservation appliances.

Effectual Object Lesson

We have established a central point where safety devices can be shown for the prevention of accidents, and an outline of the engineering requirements for the installation of safe guards on machinery, ventilation apparatus and sanitary equipment can be inspected.

We have received fine cooperation from the industrialists of the State during the two years that we have been conducting the museum, and our industries are paying a very great deal more attention to the safety of their employees, than they did prior to the inauguration of the safety first agitation. What we must have, however, is the one hundred per cent cooperation of the employees, men and women, otherwise our work will not be entirely successful.

During the past season beginning

A Differential Analysis of the Reduction in the Death Rate

Statistical Appraisal of Public Health Efforts Justifies Optimism of Health Propagandists

By I. S. FALK, DEPARTMENT OF PUBLIC HEALTH, YALE SCHOOL OF MEDICINE, NEW HAVEN, CONN.

IT IS commonly recognized that mortality statistics do not constitute the ideal basis upon which to evaluate public health activities. They are utilized, perforce, for lack of accurate data upon the incidence of morbidity in a general, mixed population. In attempting an evaluation of public health work in terms of mortality data it is interesting to compare the trends of death rates from certain groups of causes of death. From an examination of the detailed International List of Causes of Death¹ it has been possible to arrange all of the specific, acceptable titles in three summary rubrics:

I. Causes of death towards the control of which the efforts of preventive medicine have been earnestly directed during the past twenty years:

Title No.	Title
1	Typhoid fever
2	Typhus fever
3	Relapsing fever
4	Malaria
5	Smallpox
7	Scarlet fever
9	Diphtheria and croup
12	Asiatic cholera
14	Dysentery
15	Plague
16	Yellow fever
17	Leprosy
18	Erysipelas
19	Other epidemic diseases
21	Glanders
22	Anthrax
23	Rabies
24	Tetanus
28	Tuberculosis of the lungs
29	Acute military tuberculosis
31	Abdominal tuberculosis
32	Pott's disease
33	White swellings
34	Tuberculosis of other organs
35	Disseminated tuberculosis
39	Scurvy
57	Chronic lead poisoning
104	Diarrhea and enteritis (under two y. ars.)
106	Ankylostomiasis

II. Causes of death which have received little or no attention in the public health program (at least during the larger part of the period studied):

Title No.	Title
20	Purulent infection and septicemia
25	Mycoses
27	Pellagra
37	Beri-beri
30	Tuberculous meningitis
39-45	Cancer (all forms)
46	Other tumors
47	Acute articular rheumatism
48	Chronic rheumatism and gout
50	Diabetes
51	Exophthalmic goitre
52	Addison's disease

1. Based on the second decennial revision by the International Commission, Paris, July 1-3, 1909. The death rates for the years preceding as well as succeeding 1910 are based upon the 1909 classification.

Title No.	Title
53	Takemecosis
54	Anemia, chlorosis
55	Other general diseases
56	Alcoholism (acute or chronic)
59	Chronic poisonings
60	Encephalitis
61	Simple meningitis
63	Other diseases of the spinal cord
64	Cerebral hemorrhage, apoplexy
65	Softening of the brain
66	Paralysis without specified cause
67	General paralysis of the insane
68	Other forms of mental alienation
69	Epilepsy
70	Convulsions (non-puerperal)
71	Convulsions of infants
72	Pericarditis
73	Neuralgia and neuritis
74	Other diseases of the nervous system
75	Diseases of the eye and their annexa
76	Diseases of the ears
77	Otitis
78	Acute endocarditis
79	Organic diseases of the heart
80	Angina pectoris
81	Diseases of the arteries, atheroma, aneurysm, etc.
82	Embolism and thrombosis
83	Diseases of the veins
84	Diseases of the lymphatic system
85	Hemorrhage; other diseases of the circulatory system
86	Diseases of the nasal fossae
87	Diseases of the larynx
88	Diseases of the thyroid body
93	Pleurisy
94	Pulmonary congestion, pulmonary apoplexy
95	Gangrene of the lungs
96	Asthma
97	Pulmonary emphysema
98	Other diseases of the respiratory system (tuberculosis excepted)
99	Diseases of the mouth and annexa
100	Diseases of the pharynx
101	Diseases of the oesophagus
102	Ulcer of the stomach
103	Other diseases of the stomach (cancer excepted)
105	Diarrhea and enteritis (2 years and over)
108	Appendicitis and typhlitis
109	Hernia, intestinal obstruction
110	Other diseases of the intestines
111	Acute yellow atrophy of the liver
112	Hydatid tumor of the liver
113	Cirrhosis of the liver
114	Biliary calculi
115	Other diseases of the liver
116	Diseases of the spleen
117	Simple peritonitis (non-puerperal)
118	Other diseases of the digestive system
119	Acute nephritis
120	Bright's disease
121	Chyluria
122	Other diseases of the kidneys and annexa
123	Ciculi of the urinary passages
124	Diseases of the bladder
125	Diseases of the urethra, urinary abscess, etc.
126	Diseases of the prostate
127	Non-venereal diseases of the male genital organs
128	Uterine hemorrhage (non-puerperal)
129	Uterine tumor (non-cancerous)
130	Other diseases of the uterus
131	Cysts and other tumors of the ovary
132	Salpingitis and other diseases of the female genital organs
133	Non-puerperal diseases of the breast (cancer excepted)
142	Gangrene
143	Furuncle
144	Acute abscess
145	Other diseases of the skin and annexa
146	Diseases of the bones (tuberculosis excepted)
147	Diseases of the joints (tuberculosis and rheumatism excepted)
148	Amputations
149	Other diseases of the organs of locomotion
150	Congenital malformations (stillbirths not included)

Title No.	Title
152	Other causes peculiar to early infancy
153-154	Suicides (all forms)
152-154	Homicides (all forms)

III. All other causes of death; including

(a) The specific causes of death which have received some attention but which have been outside of the field of effective control because of etiological, administrative or economic factors:

(b) The causes of death in which statistical nomenclature has undergone important modifications; the ill-defined titles; the non-specific *omnia gathera* and the "cause unknown" groups:

Title No.	Title
6	Measles
8	Whooping cough
10	Influenza
11	Miliary fever
13	Cholera nostras
31	Abdominal tuberculosis
32	Pott's disease
33	White swellings
34	Tuberculosis of other organs
35	Disseminated tuberculosis
36	Rickets
37	Syphilis
38	Gonococcus infection
58	Other chronic occupation poisonings
62	Locomotor ataxia
89	Acute bronchitis
90	Chronic bronchitis
91	Bronchopneumonia
92	Pneumonia
106	Ankylostomiasis
107	Intestinal parasitiasis
134-135	Accidents, diseases, and conditions incidental to the puerperal state
141	Congenital debility, icterus and sclerema
151	Lack of care (early infancy)
154	Senility
164	Poisons, burns, traumatism
181	Fractures (cause not specified)
186	Other external violence
187-189	Ill defined or not specified

Thus, every one of the 189 specific titles of the International List is included in one or the other of the three summary rubrics, and no single item is included more than once. Before proceeding to a study of death rates for these composite groups it is perhaps pertinent to examine the basis of the groupings somewhat more closely.

It is a matter of first importance to emphasize that no attempt has been made in the preparation of rubrics I, II, and III to assign causes of death according as they are or are not controllable, or have or have not been controlled. Any classification based

upon such criteria cannot avoid the shortcomings which are inherent in conclusions based upon controversial evidences from pathology in the one case, or artificial selection in the other. Our efforts in this study are designed merely to indicate the *pros hoc* relationships between the efforts of public health workers and the trend of death rates. Accordingly, we have grouped the causes of death as they have or have not been the *objects of control* of preventive medicine. It is obvious that such a procedure can throw no conclusive light upon a proper evaluation of public health efforts. It can merely bring out certain relationships which may or may not be dependent one upon the other.

In preparing the detailed inclusions for each of the three summary groups we have been fully aware that the allocation of certain specific titles is not very clear [i. e., scarlet fever, erysipelas, diseases of the puerperal state, organic diseases of the heart, diarrhea and enteritis (two years and over), acute nephritis and Bright's disease, etc.]; that changes in the nomenclature of nosology are extremely difficult to evaluate; that the death rates corresponding to certain specific titles have been influenced by the general increases in longevity and improvements in medical diagnosis and treatment more than others; etc. Furthermore, we have been guided in a considerable measure by our convictions that in this study the growth of the public health program in the last decade must not be minimized and that the extent of public health activities of today must not be used as the sole criterion for measuring the activities of the period 1900-1920. It has been our aim to strike a balance between the work of 1900 and that of 1920, recognizing the while that the conclusions merely represent the best of our judgment.

According to the actual definition of rubric I, it would appear that under it should be listed the title of every cause of death which has appeared in any significant position upon the program of a health department. For reasons which are associated with the

individual titles, measles, whooping cough and influenza have been placed under rubric III instead of I. Because of insufficient information upon the etiology, incubation period, period of communicability, etc., the program of public health control of these diseases has been notably incomplete, particularly in the first decade of this century. Scarlet fever has been arranged in group I because it happens in this particular instance that sufficient epidemiological knowledge has long been available in place of more desirable experimental evidence to

was being waged in those years and hence the justification for its listing in Group I.

Cancer and organic diseases of the heart are listed in Group II. An extensive campaign aiming at their control is a product of the most recent years and was essentially non-existent in the largest part of the two decades being studied here. Similarly, *alcoholism (acute or chronic)* has been included in Group II because the campaign to diminish deaths from this cause has been conducted on an extensive scale throughout the country since only very recent years and was in operation in individual states for too short a period before 1920 for it to bear any relation to mortality from this cause in 1900 to 1920.

Syphilis and gonococcus infection have been given various positions of prominence in the public health work of different organizations. The sociological difficulties inherent in attempts at their control may not be minimized. Hence, these causes have been included in Group III. Titles 164-181 (poisons, burns, traumatism), 185 (fractures) and 186 (other external violence) fall into Group III because the present-day extensive campaign against accidents is a product of the last quinquennium and because earlier programs for the control of fatal accidents (chiefly industrial, mining, and railroad) have not been concerned with the numerically most important types of accidents and because many of the preventable causes of mortality in these groups have not been held to lie within the sphere

of public health problems.

The final classification has been presented in detail so that it may be examined by any who are critically inclined. The specific death rates for each cause of death were obtained from the Census Bureau Tables² for the quinquennial years 1900, 1905, 1910, 1915 and 1920 (applying to the

Figure 1.—The trend of mortality in the expanding Registration Area for Deaths, U. S., 1900-1920. (I) Causes of death whose control has been the object of public health efforts. (II) Causes of death which have received little or no attention in the public health program. (III) All other causes of death.

place the program of control on an effective administrative basis.

All forms of tuberculosis except tuberculous meningitis have been entered in Group I because the public health program for their control has been waged with appreciation of the etiological, epidemiological, and sociological factors which are peculiarly important in this particular problem. Whether one does or does not incline to accept the validity of the underlying assumptions in the anti-tuberculosis program of the years 1900-1920, the fact remains that an extensive campaign for controlling the disease

² Mortality Statistics, 1910, pp. 82-87; 1915, pp. 54-57; 1920, pp. 110-113.

³ The death rates given in the table for "all causes" are taken directly from the Census Bureau's tables. By summing the rates for groups I, II, and III, we obtain the rates 1,754.7, 1,602.1, 1,349.9, and 1,300.0 for the successive quinquennial years. The agreement is sufficiently close for the present purposes.

Welfare of Colored Workmen at Armco

Realizing the Specific Needs of Foreign and Colored Groups, Every Facility Is Provided at Maintenance Cost to the Men

IN INDUSTRIAL medicine no less than in social work, the care of the colored workman encounters many obstacles. When such employees are few in number, measures directed toward the sanitation of work places and the supervision of living conditions often fall far short of full effectiveness for these isolated groups. The American Rolling Mill Company, Toledo, O., has made unusually effective provision for foreign and colored groups. Educational classes are organized for their specific needs; and bachelors' clubs with dormitory and dining accommodations are provided.

Believing that men can give their most efficient effort only when they come to work from clean homes to work in clean, well ventilated, and safe mills, separate sleeping quarters, attractive and well cared for, are provided for the colored men. The housing service also provides cottages with garden plots when these are called for. Care for the appearance of the homes is stimulated by prizes offered each year for the best vegetable and flower gardens. A young colored woman who visits the colored families in the capacity of a friend, has organized sewing clubs and a literary circle. In the winter she teaches a kindergarten class, and in the summer supervises playground activities.

Six dormitories are maintained for the men. Facilities include a restaurant, a bath house, laundry conveniences, and a hall for recreation and assembly where there are available a barber's chair, billiard and card tables, a lunch stand, a piano, and reading tables supplied with good literature. The cost to the men is based upon maintenance charges.

The colored club hospital, opened in 1918, and maintained in connection with the club, cares for the sick as well as the injured men in this group. The hospital provision consists of

employees' organization. During the war the educational department found it desirable to put on a colored teacher of special classes in the common branches. Training classes for mechanical and electric apprentices admit all the men. The report of the educational department for 1921 shows that a total enrollment of 1,825, both white and colored was made in this department, and 286 were awarded certificates.

Apprenticeship courses are given to develop skilled molders, machinists, electricians, blacksmiths, and bricklayers. The applicants are chosen on the basis of tests as to the characteristics necessary for the chosen work. All apprentices receive pay for class room work and special inducements are offered to complete the required work. A bonus of one hundred dollars is paid to each apprentice who completes his course, and an additional bonus of fifty dollars is given to each apprentice who remains with the company six months after this training is completed. The certificate awarded is approved by the National Association of Corporation Training.

Activities, social and athletic, are many and various and employees' benefit organization takes care of all cases of injury or accidental death not covered by state insurance. It is regarded by the management that these activities have been a very real financial asset to the company, and the employees themselves aver that their best inspiration has grown out of the mutual protection and contentment which has

been a by-product of these welfare activities. Dormitory provision and recreational opportunity have likewise a health bearing that is coming to be better understood.

Dormitory arrangement provided for colored workmen during war time by the American Rolling Mill Company, Middletown, O.

waiting, dressing, and drug rooms; a kitchen, pantry, bath, two private patient rooms and two wards of ten beds each. The visiting nurses serve both white and colored families.

is under the management of the stores department. It is considered that the dining rooms are one of the most effective measures of the mutual interest work that is conducted by the em-

The Henry Street Visiting Nurse Service

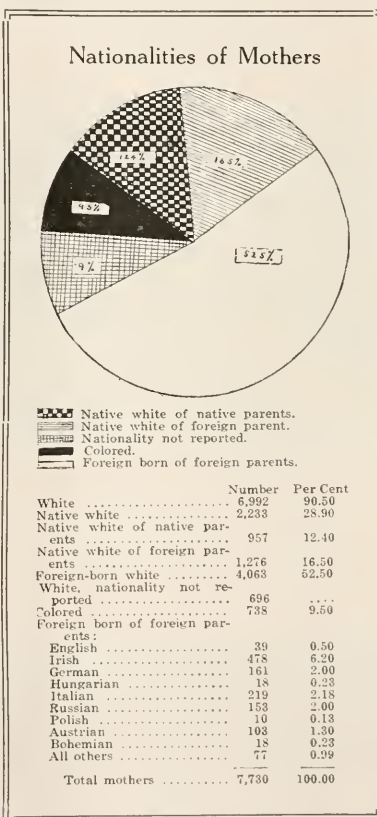

A Top Floor Apartment, with Only Two Nurses and Little Equipment, Has Its Modern Counterpart in Twenty-Three Centers

By DOROTHY DEMING, WEST SIDE FIELD DIRECTOR, HENRY STREET VISITING NURSE SERVICE, NEW YORK CITY.

JUST thirty years ago, two nurses, Miss Lillian D. Wald and Miss Mary Brewster, rented a top floor apartment on Jefferson Street, lower East Side, New York, and, associating themselves with the neighborhood, endeavored to bring skilled nursing care into the needy homes there. Even as they served, they nursed into life the embryo plan of the great visiting nurse service of today. The Henry Street Visiting Nurse Service has grown from this initial staff of two nurses to two hundred fifty. One hundred eighty-nine of these are graduate trained nurses, thirty-seven are undergraduate nurses, and twenty-six are clerical workers. The top floor apartment has its modern counterpart in twenty-three nursing centers, scattered far and wide throughout the boroughs of Manhattan, Richmond, and the Bronx. Their functions are administered, directed, and centralized in the beautiful new administration building at 99 Park Avenue. "This building is given in memory of Jacob Henry Schiff, by Therese, his wife, and is dedicated to the cause of Public Health Nursing."

The simple chart shown below will give a graphic picture of the organization of the Visiting Nurse Service as it is today.

The twenty-three nursing offices range in size from a staff of two or three nurses to thirty nurses. Each center is in charge of a supervisor or assistant supervisor or

assigned to one of the three field directors, who form a connecting link between the administrative office and the branch offices. The field directors, supervisors and staff are directly responsible to the general director of nurses.

Besides the regular members of the staff, who must be high school graduates and registered nurses in New York state, there is a body of undergraduate students who affiliate during their hospital training with Teachers College and the Henry Street Visiting Nurse Service. The students come from Bellevue, Post Graduate, St. Vincent's, Presbyterian, Walter Reed, Newton, and several other hospitals, for the undergraduate experience, in which three courses (six points) are taken at the College and twenty-eight hours per week devoted to practical field work at some one of the teaching nursing centers. A month's experience in confinement and maternity work is given to all the undergraduate nurses affiliating with the Manhattan Maternity Hospital and Dispensary. This latter experience is given at the Seventy-ninth Street Center, from which the night delivery service is carried.

Graduate nurses who have had an eight months' cruise at Teachers College are assigned to the Henry Street Visiting Nurse Service for ten weeks of field service for credit. Graduate nurses who have had an accredited course in Public Health Nursing here or elsewhere are eligible for advanced positions on the staff. An adjustment in salary is made for those staff nurses wishing to take theoretical work at the College, in accordance with the number of hours devoted to the field work. Forty-four of the present staff are taking advantage of this opportunity to increase their theoretical knowledge, without losing touch with the practical work.

The calls for the nurse are received

at the branch offices, any time during the day. The nurses report for duty at 8:30 a.m., and leave their work at 5:30 p.m. They are in the district from 9:00 to 12:30, and from 2:00 to 5:00. The average number of visits per nurse per day is eight. All calls are answered without regard to their source, but are carried only with a physician in attendance. A charge of one dollar is made for each visit or an adjustment is made in the case of families unable to meet this cost for a visit. The Metropolitan Life Insurance Company pays for the visits on its industrial policy holders. During 1922, 386,172 visits were made on 51,119 patients. Of these calls, 27.9 per cent came from the family. Each nurse cares for her own district and she carries all types of cases within that area. It is her function, not only to give the sick in their homes skilled nursing care but also instructions in personal hygiene, sanitation, and prevention of diseases, and, as far as possible, to solve the related social and economic problems that are met with in the families under her care, either by using the resources of the organization or referring the problems to the proper cooperating agencies.

The maternity service provides for attendance of a nurse at confinement, day or night, in the upper east and west sides of the city, and in the Bronx, 1,273 deliveries were attended by the nurses during the past year. A charge of five dollars is made for the first five hours of a delivery, and one dollar per hour up to ten hours thereafter. It is planned to make the confinement service a part of every staff nurse's experience in the near future. In several offices, prenatal clinics, with a doctor and nurse in attendance, are provided by the New York Maternity Center Association, at which the Henry Street Nurse assists and to which she sends patients not registered with a hospital or private physician. All babies are carried one month and are then discharged to the baby health stations maintained by the Board of Health, or to the New York Diet Kitchen Centers.

While there are uniform standards, office

routine, and equipment throughout the organization, each center offers its own special problems and developments, and diversity of experience. The nursing center in Westchester, which serves an intelligent suburban population, is as different from the one in Hamilton House, 72 Market Street, as one can well imagine. At the latter, the work is with Italian, Greek, and Chinese tenement dwellers.

The presence of the undergraduate students at certain centers brings an added zest in developing the resources of a district, not found in the smaller offices. The centers situated in the settlement houses, of which there are several, offer cooperations in health classes, examinations of children registered for clubs and classes, dental clinics, and baby-weighing clinics. There is not a center in the service which does not offer clinic experience of some type.

The services of two nurses for first aid and physical examinations of employees are provided for two factories, while a recent development has been the placing and supervision of convalescent babies in foster homes, in cooperation with the Speedwell Unit. This gives an unusual experience in Child Welfare work.

The service on Staten Island, administered by Henry Street, but under a local committee, known as the Staten Island Visiting Nurse Association, offers opportunities for community organization and the development of self-support.

Whether in Staten Island, Manhattan, or the Bronx, each nurse is striving to bring home a sense of responsibility for public health and public welfare to each family or individual with whom she comes in contact. In a few centers, small groups of cooperative people, living in the neighborhood, have been brought together and their interest in spreading health information and in bettering community health has been secured. In other areas, representatives from agencies working in the district are trying to instill this same spirit of responsibility. These community groups are calling themselves "Health Conferences," and it is hoped that the end result of their efforts will be a fuller knowledge and use among local residents of the resources offered to them, as well as an active share in the support of these services. The accompanying graph shows at a glance the proportion of foreign born maternity patients receiving the services of the nurse—52.5 per cent. In 1916, the highest number of calls for the nurse came from the physicians; in 1920, from the Metropolitan Life Insurance; but in 1922, they came from the families themselves. This evidence of an increasing popular knowledge of how to get a nurse, and the fact that the family is taking the initiative, would lead one to hope that the support from the community is increasing. At present, practically 32 per cent of the services rendered are paid for. Whether the calls from the family indicate stronger financial

backing or not, there can be no doubt that the nurse has demonstrated her educational value in the home.

A sick mother, being helped as well as instructed in the care of her children by a visiting nurse from the Henry Street Settlement.

The New York Cancer Institute is the name of new central hospital and clinic to be established under the direction of Bird S. Coler for the exclusive treatment of cancer among the city's poor. Complete equipment for diagnosis will be provided and the most highly improved apparatus will be available for high-voltage treatment. Dr. Isaac Levin, clinical professor of cancer research at the New York University, has been appointed medical director of the institute.

Everywhere Safety Pays for Itself in Increased Production

Conservation Carries Its Concomitant Saving of Time and Energy, and Comprehensive Planning Produces an Organic Whole

BY JOHN A. OARTEL, CHIEF OF SAFETY BUREAU, CARNEGIE STEEL COMPANY, PITTSBURGH, PA.

THERE are three things included in production in a manufacturing plant, which will serve as an outline of this article, *i. e.*, machinery, material, and men.

By machinery, I mean the equipment which composes the physical plant; buildings and mechanisms of various kinds. Before the advent of safety, very little thought was given by designers of buildings and equipment to the subject of accident prevention. Some of us who remember that about the first thing that occurred with the advent of safety, was that inspections were made and reports turned in recommending safeguards of all descriptions to safeguard machinery and dangerous places. I well remember that at a mill where I was employed the cost of recommendations ran into the thousands, and it was several years before they were completed. At the present time, in any up-to-date plant a very minute check is kept on all buildings and equipment planned and machinery ordered. Every blueprint, before it leaves the drawing room, has on it the magic words "Checked for Safety." All orders read, "This machine shall be fully equipped with all safety devices." National codes, state codes, and company codes, are very much in vogue, and the designing engineer has learned to consult the safety engineer before beginning a new piece of work. Now it is very much easier and cheaper to guard a machine or piece of equipment when ordering it than it is to guard it after it is installed. In a certain steel mill, not long ago, they decided to cover the gears on their overhead

traveling cranes as a safety precaution. The cranes were at least ten or fifteen years old when these steps were taken. It was found that the mechanical gang which would ordinarily do this work was very much depleted by shortage of labor and the job was given to an outside concern at a much increased cost.

Another place where safety has

two lathes were in operation. Today safety says, "Install an individual motor drive wherever possible." This is not only an enormous saving of power, but in addition, in case of an accident or break-down, the power can be quickly shut off by pressing a small push button. In former times, the only thing that controlled the speed of a stationary engine was the governor, which we know is not altogether reliable. I well remember that before the days of automatic engine stops, a large rail mill engine ran away one night. The fly wheel burst and the engineer was killed. In addition to this, a piece of the fly wheel cut the main lines that supplied light to the entire plant, which was plunged into darkness. It was several weeks before the plant could resume operations. I will not attempt to say how much production was curtailed during that time, but the plant was producing between seventy-five and one hundred thousand tons of steel rails per month. Today we have the automatic engine stop, which has saved numerous lines and thousands of dollars.

I recall an operation in a steel plant where sixteen bars were lowered into an acid solution, to remove the scales from them. The method was to use a chain sling, which remained in the acid during the pickling process. This, of course, was hard on the chain and one day it broke, resulting in the death of one of the workmen. To prevent a repetition of an accident of this nature, an additional tank was constructed and placed alongside the first one. The bars are now placed in one of the tanks, which is empty, and the chain sling is removed. The acid solution is then syphoned in from the

Safety Program Creates New Objectives

EFFICIENCY is a portmanteau word. Applied first to mechanical safeguards, it has come to carry the modern concept of complete engineering revision of the plant in methods, mechanics, and men.

But a plant is no more a business than a completely safeguarded machine is an index of safety, and it was not until the fitness and educability of the human machine entered into the safety drive that production, as the end achieved, and measured in terms of human contribution, become the true criterion of efficiency.

Wherefore haphazard methods with men have gone into the discard along with other needless hazards of industry. The incentive is yet to be found that compares with effectual performance of the day's work.

aided very much in the equipment of a plant has been with reference to power for machinery of various kinds. The former method was to have one engine drive all the machinery in the shop. This involved a complicated equipment of overhead shafting which at the very best was dangerous. The large engine would have to keep running and a full head of steam maintained in the boilers if only one or

the acid during the pickling process. This, of course, was hard on the chain and one day it broke, resulting in the death of one of the workmen. To prevent a repetition of an accident of this nature, an additional tank was constructed and placed alongside the first one. The bars are now placed in one of the tanks, which is empty, and the chain sling is removed. The acid solution is then syphoned in from the

*Read before the School for Safety Supervisors, Chicago, May 21, 1923.

other tank; the crane then takes up the bars from the tank, from which the solution has been syphoned, transfers them to a car and brings another load to the empty tank. The syphoning process is then reversed, and the load is taken from the other tank and a new load placed in it. This new process not only keeps the chain slings from the acid, but allows the crane to do twice as much work.

Handling of Material

Having completed a physical survey of the plant, the attention should turn to material going through it. It will be impossible to treat this in detail as the materials handled in American industrial plants cover too wide a range. The question we wish to answer is "How can the application of safety devices or safety principles assist or facilitate the passage of the raw material through an industrial plant until it is turned out as a finished product?" The busy executive has his eye on the cost sheets. He is not very cordial to anything that will hinder the process. We have the slogan "Safety First" that has been ringing in our ears for ten or twelve years. Does it mean anything or is it merely a catch word to attract the attention of the crowd? I have had a very good opportunity to meet executives of all kinds and to visit their plants in the last few years in connection with the work of the National Safety Council. I am happy to state that executives of all sorts all over this country are becoming more and more friendly to safety. Last Fall, I was asked to give an address to the safety council of one of the larger cities of this country, the council in this particular city being affiliated with the chamber of commerce. A dinner was given before the meeting, which was attended by the executive committee of the council and the directors of the Chamber of Commerce. At that dinner, the president of the Chamber of Commerce gave a short address, and among other things he stated that the Safety Council was the liveliest thing that had ever come into the work of the Chamber of Commerce. It was, he said, the thing that established a very vital contact between the chamber and the people of the state.

On another occasion, I addressed the chamber of commerce of a thriving city of about one hundred thousand population in the east. They were debating the question of organizing a safety council in that city. For two hours at noon those busy executives

conferred together as to the best methods of conserving human lives in that state. The point I wish to make in this is that a type of executive is growing up and being developed in this country who is sympathetic toward safety. Executives do not want to turn out products from their mills and manufacturing establishments at the cost of human lives and limbs. I have heard executives tell their foremen and men, both publicly and privately, that they want them to practise safety first even though the operation be slowed down. The big and vital problem of the safety supervisor, then, is to install methods by which the process may be not only carried on safely but also efficiently. Safety alone is a good thing, but safety and efficiency are hand-maidens whose charms no executive is able to resist.

The handling of material probably produces more accidents than any other one thing and the material that must of necessity be handled by hand labor seems to be the chief offender. In the latest bulletin of the Steel Corporation a chart is given which shows that approximately 44 per cent of all their accidents are due to hand labor. There are two ways by which this class of accidents may be eliminated, *i. e.*, substitution of mechanical equipment for hand labor and education of the workmen.

A body of safety supervisors recently inspected a steel plant in connection with a safety meeting held there. One of the party came from an old fashioned rolling mill, where the pieces as they come from the rolls are caught by a man with a pair of tongs and put into the next pass. In the mill to which the party went instead of having a man to do this work, a curved iron trough in the shape of a "U" was set up. This trough received the piece as it came from the rolls and guided it to the next pass. The man from the old time mill went back and installed one at his plant. At one particular place in his plant four men were engaged in the work I have described. The installation of this device eliminated these four men and thereby prevented them from ever being injured and in addition the company is saving five thousand dollars per year by the installation.

At one plant engaged in the manufacture of small bars, two units of the plant were located on opposite sides of a city street congested with traffic. One part of the process required that the bars be transferred across the street from one unit to the other. This was accomplished by trucks

drawn by horses, in all, eight horses and their drivers. A change was made a few years ago by substituting gasoline trucks for the horse-drawn vehicles. This substitution eliminated the possibility of accident to horses and drivers alike on account of lack of control on the busy street. Now they have a mechanism which is at all times under perfect control and the company thereby saves fifteen thousand dollars every year.

The Personal Equation

The last factor in this discussion is men, by far the most important and interesting. In the beginnings of the safety movement it was thought that with perfect engineering revision and with plants completely safeguarded, accidents would be eliminated entirely. The fact is, that safeguarding has only eliminated from one-fourth to one-third of them. I am familiar with a plant that is the last word in safety as far as construction and equipment is concerned. The machinery is electrically driven; in fact there is only one fifty horse-power boiler at the plant and that is used for heating purposes in cold weather. There is very little if any hand labor, and an elaborate system of subways connects the various departments, so that men do not need to cross tracks or go near any moving machinery. Yet, notwithstanding the elaborate physical precautions taken to insure safety, this plant has had a greater accident rate than similar plants under the same management which are older. The reason is that not enough consideration has been given to the personal element. It is a strange thing that with all the developments and refinements of civilization and education, human nature is practically the same today as it was when the world was young. Man is not born with the safety habit but acquires it from education and experience. The National Safety Council, through its foreman's instruction courses has been an important factor in the last few years in educating a large number of foremen all over the country, who have in turn educated the men over whom they have supervision. I know of a steel plant in the Pittsburgh district which one year sent a hundred or more of its foremen to the National Safety Council safety instruction course. The foremen were so enthusiastic about the course that they asked if a similar course could be conducted in the mill town for all the foremen at the plant. This was accordingly done and a course of six lectures was con-

Editorials

The news of the death of Dr. Hermann Michael Biggs, commissioner of health of the state of New York, has come with a sense of

deep personal loss to every health worker in the United States and to innumerable friends and colleagues on the other side of the Atlantic.

Dr. Biggs
Passes
1859-1923

Dr. Biggs was a graduate of Cornell and of the Bellevue Hospital Medical College. He taught pathology and, later, medicine, at Bellevue, served as first director of the Carnegie Laboratory, as pathologist and, later, general medical officer of the New York City Department and finally as State Commissioner of Health. He was a director of the Rockefeller Institute for Medical Research and a member of the International Health Board and occupied positions of leadership in various organizations devoted to the control of tuberculosis and other aspects of the public health campaign.

Memories innumerable, of notable achievements for the cause of public health, crowd into one's mind in looking back over the period between 1859 and 1923 covered by this rarely fruitful life. The establishment of the first municipal bacteriological laboratory in the world and the organization of the first comprehensive municipal program for the control of tuberculosis, the introduction of diphtheria antitoxin into this country, service in all quarters of the globe as a member of the International Health Board, and medical director of the League of Red Cross Societies are among its individual outstanding achievements.

These were all parts, however, of a broader general program and it is as America's chief sanitary statesman that Dr. Biggs will be most widely remembered. As general medical officer of the New York City Department of Health from 1901 to 1914 and as commissioner of health of the state of New York from 1914 until the time of his death, Dr. Biggs was the guiding and impelling force in building up the strongest city health department and the strongest state health department in this country and perhaps in the world. These two organizations stand, and will continue to go forward, as living monuments to his memory. He built these departments soundly

and firmly on the basis of science; and the important part played by the health laboratory in American public health is largely due to his influence. Through a period of twenty years he made scientific knowledge bear fruit by dealing with political leaders of both parties in such a way that they respected him and loved him. He was wise as the serpent in avoiding needless complications and brave as a lion in meeting every issue of principle. The health center law upon which we comment below was only the latest in a long series of triumphs due to his vision.

Above all, however, there is left to us who knew him the memory of a rare and precious personality. He performed the miracle of combining tireless and efficient public service as a health administrator with preeminence in his original profession which maintained him in the front rank of internists in this country. Over professional colleagues and associates, over politicians and patients, he exercised a personal magnetism which made him primarily a leader of men. Those who had the privilege of working with him felt to him the absolute devotion that is given to a great military leader. He was indeed a captain in the war against disease, whose victories won freedom for thousands from the bonds of suffering and of death.

Three years ago reference was made in these columns¹ to the recommendations made by Governor Smith of New York, during his first term,

New York Sanitary Statesmen

for the development of health facilities in the rural districts. This measure of which we said editorially "Probably never before in the history of this country

has so far-reaching a measure been proposed by responsible authorities," failed of passage by a narrow margin in the 1920 legislature. Governor Smith is once more in the capitol at Albany and in a special message under date of April 11, 1923, he called attention once more to the serious situation created by the lack of medical service in the rural districts and recommended the enactment of legislation providing that "when the county supervisors of counties having no first or second class cities, undertake public health work and make an appropriation therefor, either for small community hospitals in rural districts or public health activities of any other kind, the State shall appropriate a similar amount, dollar for dollar. The work to be done must conform to the standards of the State Department

of Health and any money supplied to the county must be upon certificate of the State Commissioner of Health that the work is necessary and is satisfactorily done and conforms to the standards of the department."

As a result of this message, Assembly Act 2392 was approved by the legislature² with the following fundamental provision:

Whenever the board of supervisors of a county, exclusive of a county having within its boundaries a city of the first or second class, shall appropriate and expend moneys for the construction, establishment or maintenance by such county of a county, community, or other public hospital, clinic, dispensary or similar institution, or for the purpose of defraying the expenses of such county in any public enterprise or activity for the improvement of the public health, or any public health work undertaken by such county, such county shall receive state aid in the manner and subject to the conditions prescribed in this article. The legislature from time to time shall make appropriations for the purpose of rendering such state aid.

Among the other bills approved by the General Assembly of New York was one amending the public health law in relation to general health districts which provide that after the board of health of a general health district has prepared its estimates of expense and the board of supervisors has inquired into the necessity for the various items involved, the board of supervisors shall levy a tax on the real and personal property within the limits of the district sufficient to meet the expense deemed necessary, and that in making such an estimate "the Board of Supervisors may lawfully include therein and approve of items of expense which may in any degree tend to promote the efficiency of the administration of the provisions of the public health law and other regulations adopted in pursuance of the authority thereof." (Assembly Bill, No. 1681.)

Assembly Bills Nos. 2038 and 2359 deal with the provision of local laboratory service permitting the board of supervisors of any county to establish a public health laboratory for a definite area services of the laboratory to be rendered at a moderate charge or fee. Upon the petition of two hundred or more tax-payers the governing board is required to hold a referendum on the question of establishing such a laboratory. And when county or district laboratories are thus provided under general conditions laid down by the state department of health, state aid is to be granted for the maintenance of such laboratories.

Taken together, these bills represent one of the most significant developments in the history of American public health practice. Their passage was made possible, first of all, by the statesmanship of Health Commissioner Biggs and the

1. Modern Medicine, iv, 269 and 276, April, 1920.

2. See page 194 of this issue for the full text of the bill.

vision of Governor Smith and, second, by the wise policy pursued in calling together in February the leading medical men of the state for the consideration of these problems—a procedure which succeeded in enlisting the support of the medical profession for the policies proposed. By this legislation the state of New York is definitely committed to the policy of state aid to rural communities for the development of a public health program on the widest possible scale. The results will be watched with the keenest interest by public health workers throughout the country and should be fraught with far-reaching benefits for the health and welfare of the citizens of the state.

Considerable concern has been evinced by public health workers as to the possible lessons to be drawn from a comparison by Professor Raymond

Public Health Does Pay

Pearl of the rate of reduction in the death rate from certain "controllable" and "non-controlled" causes of disease¹. As controllable causes of death Pearl selects

tuberculosis of the lungs, typhoid fever, diphtheria, and croup and dysentery, a classification to which no reasonable exception can be taken. For non-controlled causes of death, on the other hand, he chooses bronchitis (acute and chronic), paralysis without specified cause, purulent infection and septicemia, and softening of the brain, and, to this selection, practical vital statisticians will have the most vigorous and well founded objection. The author states that he chose these four diseases at random from among the causes of death whose rates he knew to be declining. In other words, they are obviously selected to show that some causes of death, other than those easily controllable, exhibited a reduction. The choice of these particular titles would seem, however, to be a singularly unfortunate one. All four of them and particularly the last three are indefinite and unsatisfactory terms which registrars have for years been trying to eliminate by returning death certificates and asking physicians to substitute other causes of more definite significance. The reduction in the apparent death rate from the last three of these causes, and in part from the first, is beyond question simply a matter of better statistical classification, the deaths earlier reported under those unsatisfactory headings being transferred to others².

It seems well worth while to consider this question of reduction in controllable and non-controllable causes of death from a really comprehensive basis. This has been done in the present issue of *THE NATION'S HEALTH* by Dr. Falk, who has divided all causes of death in the International List under three general rubrics and has analyzed and plotted the results. There will no doubt be differences of opinion in regard to particular items as to whether they should be classified as "causes of death toward the control of which the efforts of preventive medicine have been earnestly directed during the past twenty years; causes of death which have received little or no attention in the public health program at least during the larger part of the period studied; and all other causes." In general, however, the basis of classification seems sound, and all seriously doubtful causes of death like measles and whooping cough (which we have attempted to control, but in regard to which we have obviously failed to secure the necessary cooperation from the public), venereal diseases (where an effective campaign on a general scale has only been carried on since the Great War), pneumonia and bronchitis, (where a knowledge of effective control measures is still woefully incomplete) and accidents, (where except for certain industrial efforts the campaign of prevention is very recent) are included under heading III.

It appears from Dr. Falk's study that the group of causes of death which have been subject to a definite and purposeful public health endeavor have been reduced in twenty years by 54 per cent, that the group which have not been subject to any comprehensive plan of control have been reduced by only 10 per cent, and that the doubtful intermediate group shows a reduction of 25 per cent. The first group of causes according to Falk's classification accounted in 1920 for less than 2 deaths per 1,000, the second group for 8, the third for 4. It would seem then that a fair and comprehensive analysis of the statistical material at our disposal furnishes a complete vindication of the achievements of the modern public health campaign and stimulates us to transfer our aggressive efforts to the causes in the last two groups, many of which are today recognized by the progressive health worker as presenting substantial promise of a possible control. Though during 1900-1920 there has been a general decline in the death rate from all causes, such a shift in health emphasis would in all probability mark the less favorable groups by the same substantial reduction that Group I records during the past twenty years of health effort.

Educational Tendencies in Britain

On both sides of the Atlantic there is an encouraging awakening to the need for a changed atmosphere in the medical school. Three recent addresses by American authors¹ have forcibly emphasized the importance of the preventive viewpoint which is still so commonly lacking in the training of the medical student—and now from Sir George Newman, chief medical officer of the Ministry of Health and of the Board of Education of Great Britain, there comes an admirably clear and convincing statement of the same point of view.²

With certain of Sir George's specific recommendations in regard to the content and spirit of the medical curriculum we are not here directly concerned, although the following four major conclusions are strikingly in accord with the best tendencies of the moment in America.

(1) The necessity of integration of chemistry and physics into physiology and pathology, of physiology and pathology into medicine, surgery and obstetrics, of the laboratory into clinical study, of the science into the art—that each of these aspects shall be taught in principle and not overburdened with detail, in such a way as to allow the student to reflect and comprehend and grow—this is the first and fundamental requirement.

(b) Secondly, clinical study must remain the sheet anchor of English medical education and must be strengthened both in technic and understanding. The student must be so trained as to be able to stand alone in clinical skill and judgment.

(c) A plea for a lightening of the load imposed by examining boards; and

(d) Emphasis on the importance of the organization of postgraduate courses for advanced or special studies, "refresher" courses.

The part of Sir George's report which is of particular moment to the readers of THE NATION'S HEALTH is that which emphasizes the part to be played by preventive medicine in private practice and the importance of special advance training for the professional public health worker. The medical practitioner, as he says, "is and must remain, not only one of the principal interpreters of prevention to his patients and to the public, but he himself should be a discoverer and practitioner of prevention." The physician must therefore be soundly trained not only in personal hygiene, "strangely neglected in medical schools," and not only in the etiology of disease but in the place and purpose of sanitation in a hygienic environment and in an evaluation of the effect on health and disease of social evolution. The General Medical Council, which has just prepared a

new curriculum, recommends that the subject of preventive medicine "should be a pervading influence all through the curriculum, affecting every subject in it, so that the student naturally and almost unconsciously adopts in his daily practice of medicine the attitude and spirit of scientific prevention. He acquires a ready preventive habit. As Horatio says in Hamlet, 'Custom hath made it in him a property of easiness.'"

"First, therefore, of the ways and means of teaching preventive medicine is for teacher and pupil to see the subject as it really is, and not as it appears to be. No man can understand prevention without regard to the science and art of medicine. The first step in the study of this subject is to give it a correct setting *among the clinical subjects*, for there it belongs. It borrows from the basic sciences and acts upon internal medicine, surgery, and obstetrics; and it lends inspiration to them all. No longer is it to be considered a Cinderella, no longer a mere appanage of the curriculum, no longer 'drains' and a nuisance. It has become the *ultimate* purpose of the whole."

Dr. Fred Banting of Canada read in a surgical journal of the effect of tying the pancreatic ducts. From this article his physiologically trained mind

conceived the idea that a properly prepared extract of the pancreas, freed of its digestive action, would prove beneficial in the treatment of diabetes in man. Dr. J.

Insulin: Its Field of Usefulness

J. R. Macleod, professor of physiology at the University of Toronto, and long a student of diabetes, became interested; the idea was experimentally tested in the laboratory and in a surprisingly short time results of the utmost importance were announced. A patent extract was made; it was called insulin. This in brief is the dramatic story of one of the most sensational episodes in modern medical history.

The relation of the pancreas to the disease, diabetes mellitus, has been known for over thirty years. Experiments on dogs have shown that removal of the pancreas resulted in diabetes and that the severity of the resultant diseases depended mathematically on the amount of pancreas removed. Despite many attempts to carry this knowledge into the field of therapeutics, and despite the fact that pancreas extracts were made and used on man at least as early as 1908, no investigator up to Banting carried the matter to the logical conclusion. To Banting, then, belongs

the credit for the discovery; and to "The Toronto Group" the glory for their vision, their painstaking care in the animal experiments, and their early generosity in sharing their knowledge.

Already insulin has been used in a sufficient number of cases to permit an evaluation of its usefulness. It is definitely not a "cure"; its discoverers have never claimed it to be a cure. It has the power of allowing the diabetic organism to burn sugar, thus causing urinary sugar to disappear, and blood sugar to drop to normal. Properly given, it will bring patients out of diabetic coma; it allows surgical operations on even the severest diabetic. In children it has a particular field of usefulness in permitting development and growth where formerly the course was steadily down-hill to death.

But despite the brilliant results which all students of insulin confirm, it must be remembered that it has potency for evil as well as for good; in this respect differing in no way from morphin, digitalis or other powerful drugs. Given in overdoses it may produce "tremblings," convulsions, or even death. It should not be used without careful control of the diet. So far its value has been demonstrated only when given hypodermically daily, in doses large enough to control the sugar excretion without producing toxic reactions; and as yet no one has found that the effects of insulin persist when its use is discontinued. In brief, it is a powerful agent for good when properly used and when steadily used. The effect it already has had and will have on the health of the community is not difficult to estimate. If there are more than half a million diabetics in the United States (as one author has stated) it will mean that health and economic efficiency will be restored to a large mass of population—a result hard to measure in mere figures and yet as promising in its prospects as has been the practical elimination of typhoid fever.

Announcement has been made of the retirement of Dr. S. Josephine Baker as director of the Bureau of Child Hygiene of the Department of Health of New York City. In 1922 Dr. Baker completed twenty years of service in the Department and in retiring from active service she leaves a remarkable record in the efficient and well organized Bureau of Child Hygiene, through whose work the health of the children of city and state has improved so

A Child Hygiene Pioneer

greatly. This bureau was the first one of its kind to be established in the United States and Dr. Baker was its organizer and has been its director since it was started. It has served as a model upon which all similar work for child health has been formed. At present forty-four states and practically every city of importance have organized bureaus of this type. When the Bureau was started in New York City in 1908, 144 babies died each year out of every thousand born. Last year only seventy-five babies died out of every thousand born and, as a result of this work, New York has had for several years the lowest baby death rate of any city of its size in this country or in Europe.

Last year Dr. Baker received the honor of being appointed as a representative of the United States on the Health Committee of the League of Nations. She is consultant in Child Hygiene to the United States Public Health Service and the New York State Department of Health. She is also a member of the faculty of Columbia University and of New York University as well as the author of various books and articles on child welfare. It is to be hoped that in retiring as director of the Bureau of Child Hygiene, Dr. Baker will be able to devote more of her time to work in other fields and thus extend her interests and influence. She has proved herself a public servant of a type only too rare in any country and we shall count on her unofficial leadership in the field of public health for many years to come.

Comby's figures on the rate at which tuberculosis is found in children less than two years of age are thought-arresting. Comby records no

Tuberculosis in Childhood

cases occurring before the age of one month; 2.5 per cent of his cases occur between the age of one and two months; 3.33 per cent between two and three months;

15.15 per cent from three to six months; 25.86 per cent from six to twelve months; and 46.05 per cent between twelve and twenty-four months.

Hoffa since 1919 has made it a routine to do a Pirquet reaction on all children admitted to the hospital at Barmen. These children belonged almost exclusively to the poorer classes and perhaps give a higher tuberculosis rate than would a cross section of the infantile tuberculosis rate of the entire community. Children giving a negative reaction were re-tested after a few days and if the negative results still persisted, an intra-

1. Klin. Woch. 1, 1922, p. 885.

dermic reaction test was applied. Hoffa's results from May, 1919 to December, 1921, inclusive, are as follows:

Age	Percentage positive
0—3 years	25.7
4—6 years	39.9
7—10 years	50.5
11—14 years	63.1

In comment on these results², it is pointed out that these figures do not parallel those published by Sanders for the city of Dortmund but are a little higher because Hoffa did not, like Sanders, subtract the already proved cases of tuberculosis. The figures of Umber for Charlottenbourg and of Moro for Heidelberg are about the same. Hoffa believes that practically all of the children in large cities are infected by the tubercle bacillus. He has made similar studies, but by the cutaneous reaction only, in many other institutions for children and with about the same results, if it is assumed that the intradermic tests give percentages about ten or fifteen per cent higher than those made cutaneously.

Familial contagion is the dominant factor in a large proportion of cases and, as might be expected, a tuberculous mother is far more dangerous in this respect than is a father having tuberculosis. Thus L. Ribadeau-Dumas³ states that the mortality of children with a phthisical mother is 33.5 per cent while among those having a tuberculous father only, it is 14.7 per cent. Indirect infection by articles contaminated with tuberculous sputum is always possible but probably does not play any great rôle as compared with direct contact with an active case of tuberculosis. The use of unpasteurized milk is obviously the most frequent source of cases of the bovine type.

Rivadeau-Dumas believes that the incubation period is relatively short, roughly about thirty days, and that the progress of the disease depends to a certain extent upon the age at which the child is infected and the size of the dose which he receives. He suggests that a single dose is more harmful than the same amount in small divided doses; in fact, the latter (which unfortunately cannot be controlled) may have an immunizing effect. Children infected before the third month almost invariably die; under one year, the mortality is stated to be 86 per cent from one to two years, 10.8 per cent; and from two to three, 2.7 per cent.

It seems as if the foregoing facts indicate fairly definitely that the point of election in the prevention of tuberculosis is the period of childhood. Since the origin in the bulk of cases is familial, every effort must be made to isolate infants from open tuberculosis cases, whether other children

or adults. To do this effectively, it is first necessary to know where these cases are, then to determine whether or not they are in contact with children, particular attention being paid to infants. It should be recognized that the open case of tuberculosis is a menace to society, since it is dangerous to the oncoming generation, and society should provide the means and the authority whereby children may be taken out of such an environment or the tuberculous person is removed therefrom. Naturally, this will at times be very hard to accomplish. Economic conditions, sentiment and prejudice will all be interposed, but they should never be allowed to stand in the way. Institutions must be provided for children removed from a tuberculous environment, and funds supplied for the support of families from which the tuberculous wage earner is removed or from which the tuberculous mother has been taken. Every endeavor must be made to protect the health of the children left behind.

As an element in this policy, every infant coming under the observation of a physician should as a routine be given a Pirquet reaction test, since the clinical diagnosis of tuberculosis in nurslings before extensive involvement has occurred is so exceedingly difficult.

In a recent communication Lee and Van Buskirk¹ review a long series of proposed physical tests for diurnal fatigue and find that none of the cardiovascular constants studied, nor the Ryan skin reaction, nor the Flack and other respiratory tests, nor the resistance strength test of Martin, is sufficiently

delicate to detect the physical fatigue resulting from a fourteen mile walk. Their study indicates some very interesting though slight differences between the average cardiovascular states of fatigued and unfatigued groups but reveals no constant significant differences between the fatigued and unfatigued, in the individual case.

No sooner are old tests for fatigue discarded than new ones make their appearance and a particularly interesting and suggestive contribution to this subject has just come to us from Belgium². It depends on what is known as the "illusion of equal weight," the tendency of the normal individual to assume that of two objects really equal in weight the smaller one is heavier. In the use of the test which is based on this fact a small ball

New and Old Tests for Fatigue

of constant weight is taken and the subject is given a series of large balls of varying weight to select the one which seems equal to the small one. Both hands are used, the balls being passed from one to the other freely. The conclusions drawn, illusory though they may be, represent a rather complicated neuro-muscular response; and, when the illusion decreases, the greater accuracy in estimating the weight of the balls indicates a less perfect functioning of the bodily reactions, even though it does lead to more correct results. Dr. Ley finds that the illusion of weight is quite definitely decreased by the ingestion of 25 grams of alcohol in the form of cognac and that it is also quite definitely decreased by fatigue, results in regard to the latter point having been obtained by comparing reactions of nurses on night duty with the same nurses under ordinary conditions. Whether this test for fatigue and for the effect of alcohol will succumb to further criticisms, as have so many other similar tests, remains to be seen.

The statistical studies of Drury¹ and Hoffman² have shown that the inhalation of silica dust is in some way responsible for a high rate of mortality from tuberculosis.

Studies on Pneumo- koniosis

But statistical studies obviously cannot supply the information necessary for the solution of this problem. The problem of dust inhalation and industrial tuberculosis is now beginning to receive the attention it warrants from the laboratory worker.

The studies of Mavrogordato³ in England and of Gardner⁴ at the Saranac Laboratory have clearly shown that the inhalation of silica dust by laboratory animals renders them more susceptible to tuberculous infection and that, once infected, the lesions tend to clear up less rapidly than do the lesions in undusted animals. Statistical studies in the marble industry have failed to associate this industry with a high tuberculosis rate. Recent laboratory studies⁵ on the inhalation of marble dust indicate that the reason for its harmlessness lies in the fact that this dust is in a large measure

soluble in lung tissue. This suggests an explanation as to why workers in the marble and lime industries do not suffer such high mortality rates from tuberculosis as do those engaged in atmospheres charged with silica dust. Coal dust inhalation among miners has in general been associated not with an increased rate from tuberculosis, but rather with a rate lower than that found for all occupied males. The reason for this has until recently been lacking. By the work of Willis⁶ we now learn that after guinea pigs are exposed to coal dust in large quantities even over a period of one year, less dust is found in their lungs than is found in normal, undusted laboratory animals two or more years old. It would appear that the inhalation of large amounts of coal dust sets into motion some mechanism by which the dust is eliminated as rapidly as it enters the lung tissue. A complete explanation for this phenomenon is still lacking. A contribution which probably has an important bearing on this process has been made by Fenn⁷. Working with carbon and quartz dust he found that carbon was ingested approximately four times as readily as quartz dust. It is conceivable, reasoning from this, that the carbon dust is brought to the trachea and later expectorated whereas silica remains in the alveoli.

The British workers have proceeded along different lines in their investigation of this subject. Recently Cummings⁸ has shown that silica dust destroys the action of complement in vitro. Gye and Kettle⁹ of the National Institute for Medical Research of London have attacked the problem somewhat more directly than Cummings. These authors have shown that the subcutaneous injection of silica and tubercle bacilli simultaneously gives rise to lesions of longer duration than those produced with the tubercle bacillus alone. They explain this end result by saying that silica is a cell poison which breaks down the cellular defenses and permits the tubercle bacillus to proliferate. It is significant that these workers have obtained practically the same results with carbon as with silica dust. It would seem therefore that for the present at least the findings of Fenn constitute the most tenable explanation for the differential behavior of carbon and silica dusts in the causation of industrial tuberculosis. It appears that silica dust cannot readily be removed from the lung, it accumulates in this organ as a foreign substance, and interferes with the normal defense mechanisms of the lung.

Year's Progress of Mansfield Demonstration

AT THE close of its first year of activity the Child Health Demonstration of Mansfield, Ohio, held an official opening of its home offices on January 20, 1923. The object of this open house was to show to the citizens of Richland County the extent to which the demonstration had developed during the year just passed.

The origin, policies, and preliminary steps that were taken to place the demonstration on a sound working basis have been described by Dr. Walter H. Brown in an article contributed to THE NATION'S HEALTH in September, 1922.

The work of the medical service of the Child Health Demonstration, carried out through health centers and consultation service, is under the direction of Dr. J. Hart Davis. Since July 5, 1922, there has been a steady increase in the enrollment of well children in the health centers of the county until it now totals 374. During this time 962 visits have been made to the centers by these children.

Through these centers the following services have been offered to the public: (1) weighing, measuring and physical examination of children; (2) discussion and advice on diets, habits, and hygiene; (3) formulas for infants with the understanding that the family physician does not object to such service; (4) distribution of printed diet slips for children of various ages over one year; and (5) a consultation service by which any physician, or any family through their physician, can secure free of cost the services of the director of the medical department.

No attempt is made by the department to force their services, and none is given unless requested or permitted by the family physician.

The demonstration is not developing a nursing corps of its own. It is helping the Mansfield Public Health Nursing Association, the Richland County chapter of the Red Cross, and the Shelby Health League to develop a county wide nursing service. Under the direction of the family physician care is being given to expectant mothers; assistance given the doctor at the time of the delivery; and the care of both well and sick

the physician make the examination. Signed consents were shown by 60.25 per cent of the children and 14.7 per cent had a parent present at the examination. Last fall the nurses began their regular school work and before January 1, made 5,481 inspections.

One of the major projects of the demonstration is health education, and through the cooperation of the educational authorities, teachers, and

parents ways are being worked out to make health habits attractive to children. Health is being taught through different subjects in the curriculum and by such direct measures as institutes, conferences and lectures. The "Rules of the Game" and the Junior Health Department are already stimulating children to better health habits.

A most successful health institute was held at the high school September 5-8, 1922. A pageant, entitled "Happy,

the Pied Piper of Healthland," written and directed by Mrs. Ethel Beard-Barrett then director of health education, was given by two thousand children at the county fair. Miss Elma Rood is the present director of this department.

Monthly weighing and measuring, physical education in school hours, group athletics on the playground, and competitive athletic meets at the end of the school term are other activities along the line of health education.

The nutrition department, under the direction of Miss Edna C. Endly is furnishing assistance assuring every child an adequate school lunch. In Mansfield and the other high schools complete lunches are served, and in the rural schools "one hot dish a day" is rapidly becoming popular.

Corps of nurses from Demonstration leaving headquarters to go on daily mission.

children from birth to adult life.

All first calls for the bedside care of ill persons are answered by a nurse but a patient is not revisited unless a physician is in charge.

Under the direction of Miss Helen F. Boyd the nursing force of the county has been increased. There are now seven nurses in Mansfield who made 8,316 visits during the past year, and three nurses in the rural area made 3,102 visits. Two nurses are employed in Shelby. A new set of nursing records were installed on April 20, 1922.

Health examinations were begun in the third and fifth grades of both the public and parochial schools. In the examination of 1,119 children the provision was made that the written consent of the parents or their presence would be necessary in order to have

In cooperation with the Federation of Women's Clubs, the nutrition service aids in serving milk to children who are ten per cent or more underweight. During the past year seven hundred such children have received such additional nourishment twice daily in the public schools. Home economic courses in the high schools and mother's classes teach proper food selection and preparation. In the classes held for mothers special attention is given to the nutritional needs of the child.

The human book-keeping of the Child Health Demonstration is carried on by the research department of which Miss Emma Duke is director. It is interested in just how many children in the community are healthy and in any conditions that may influence their health. It is engaged in measuring the effect of the work being done by the demonstration; in ascertaining what benefits are derived from the nursing service. It seeks to determine if health education does improve the health habits of the child, and if it is worth while to give milk to underweight children in the schools. By answering these questions the community will have a basis for judgment in determining which activities it wishes to continue when the demonstration is completed.

Life Insurance Medical Examinations

In an address delivered at the sixteenth annual meeting of the Association of Life Insurance Presidents in New York City, December 7, 1922, Dr. Augustus S. Knight, medical director of the Metropolitan Life Insurance Company said that heart disease, Bright's disease, and cerebral hemorrhage reduce the life span a total of about four years.

An extract from Dr. Knight's paper on "Life Waste in 1922—Its Warning and its Lesson" follows:

The insurance medical examination puts into our hands an opportunity for health service which we have not developed at all. Every year the records of our companies show from 7 per cent to 10 per cent of applicants rejected or postponed for insurance. These persons show at examination all types of disorders and impairments. All of them are important, and a large number are remediable under proper care. Each year, of the persons rejected for insurance about 15 per cent, the figure varying somewhat from company to company, have indications of incipient or advanced nephritis. Five per cent of the rejected persons are either diabetics or are judged likely to become such. Over 10 per cent have suspicious respiratory signs, or have active respiratory disease. About a quarter of them have

one type or another of heart impairment. A small proportion, indeed, are of such generally low physical grade as to warrant rejection, although lacking in any particular outstanding organic impairment. It is our experience that a goodly proportion of these applicants are absolutely unaware of what is the matter with them, and learn for the first time of the existence of the impairment when the notice of rejection reaches them. Consider what it means for a person who has in good faith asked for insurance, to be told that it is not available to him because he is suffering from one or another disease. That man's attitude is often one of angry disappointment, but his second reaction is one of inquiry into his state of health and of determination to do all within his power to make himself physically fit.

The psychology of the situation is entirely a favorable one for performing constructive, remedial work. Yet, in spite of that, most of us do hardly anything to assuage the disappointment of the individual or to help him get well; perhaps we incur his resentment. In any event we *waste* an opportunity for making a friend and well-wisher out of him. We should, I believe, work out a way of informing rejected and postponed applicants of the causes for rejection or postponement and in every case where we can safely do so and by that I mean every case where the medical findings are so positive and indisputable that disclosure would not involve opposing opinions and consequent persecutions of the local medical examiner following discussions with the family physician and applicant—a situation that must always be avoided. We might, too, carry through our stroke and suggest that he place himself under proper medical supervision and give him reason to believe that he may become insurable in the future. I am convinced that the time is ripe for our companies to lead the way in suppressing this prevailing waste of opportunity for signal public service, and to work out a method by which the valuable information on the applications can be made available to the rejected and postponed applicant. This service should include, also, those persons slightly impaired who are taken on standard plans.

But this is only the beginning. Many a man is accepted who shows on the examination record evidence of some minor impairment, not sufficient to warrant rejection or to question his insurability, and yet important enough from the point of view of the individual's welfare and of his family to justify intelligent, effective follow-up, with the giving of helpful advice.

Medical examinations are an expensive part of the cost of life insurance administration. We can easily make them worth all that they cost, and a great deal more, through the simple expedient of the periodical follow-up examinations of the persons insured with us. Fortunately, this matter is no longer in the experimental stage. For a period of eight years, the Metropolitan Life Insurance Company has to an ever increasing degree encouraged its policyholders to take advantage of the opportunity to be examined periodically at

the company's expense. I had occasion last year to evaluate the results of this work and undoubtedly you are already fairly familiar with our findings. We were able to show that those who were examined in 1914 and 1915, for a period of five years following the examinations, showed a mortality 28 per cent more favorable than that for the entire Ordinary Department in the same years. We further calculated that the saving in mortality gave a return of two dollars for every dollar expended for the insurance examinations. These figures are all rough, but I quote them to show why we in our company are convinced of the value of the periodical physical examinations. When properly conducted, periodical examinations with appropriate advices, are effective as a means of avoiding life routines that lead to disease, of controlling minor impairments, of minimizing and slowing down the progress of the major ones, and of maintaining a high standard of individual health. We are more and more opening the door to our policyholders for this service, so that at the present rate we hope and expect to make 25,000 examinations in the year 1922 among Ordinary policyholders.

Kansas City Health Conservation Association

The Health Conservation Association of Kansas City has been organized as a union of the Kansas City Tuberculosis Society, the Social Hygiene Committee, the Mental Hygiene Committee, the Dental Hygiene Committee, and the Cancer Control Committee. From this representation an executive board of twelve members and the officers are elected, the separate societies serving as divisions of the larger organization. The president and the executive secretary of the Tuberculosis Society were made president and executive secretary, respectively, of the association. The organization is a part of the plan being developed through the Council of Social Agencies for the more effective coordination of voluntary welfare agencies.

New Hampshire Needs Rural Physicians

New Hampshire has passed a law effective April 5, which permits any town to raise money toward the support of a resident physician which in the absence of such appropriation, could not obtain one.

The *World's Health* reports results of the recent comparisons by countries of per capita consumption of opium as follows: Italy, 1 grain; Portugal, 2.5 grains; France, 3 grains; Holland 3.5 grains; the United States, 6.3 grains.

Health and Physical Education in the Schools*

Report of Surveys Made By Chambers of Commerce of the United States

IN OCTOBER, 1921, the civic development department of the National Chamber of Commerce issued in its series of pamphlets on "The Schools of Your City," one on the subject of school buildings and equipment, and in May, 1922, one on health and physical education. With these pamphlets there were sent to chambers of commerce, question blanks to guide education committees in making surveys of the elementary schools in their community.

Up to the time this is written sixty-one cities have sent into the National Chamber their findings on school buildings and equipment and 160 those on health and physical education. Thirty-six sent in the results of both surveys.

Of the sixty-one cities making returns on school buildings and equipment, representing 28 states and one territory, one has a population of over 300,000; three from 100,000 to 300,000; six from 50,000 to 100,000; seven from 25,000 to 50,000; thirteen from 15,000 to 25,000; six from 10,000 to 15,000; thirteen from 5,000 to 10,000; and twelve below 5,000.

The number of schools examined in the 61 cities was 701. Of 579 buildings of which the date of construction was reported one school was built prior to 1840; two between 1840 and 1850; three between 1850 and 1860; twenty-three between 1860 and 1870; forty-nine between 1870 and 1880; seventy-nine between 1880 and 1890; ninety-four between 1890 and 1900; 124 between 1900 and 1910; 142 between 1910 and 1920; and sixty-two between 1920 and 1922.

These figures raise the question as to the proper life of school buildings throughout the United States, particularly as experts state that the average life of school buildings in the United States is not over thirty years. Within the past few years there have been advances in knowledge concerning proper lighting, ventilation, sanitation, fire prevention, and artistic design which have caused many communities to abandon school buildings

structurally sound and usable and erect in their places others which conform to modern standards. The life of school buildings erected from now on should be much longer than those of an earlier period if the proper attention is paid to essentials at the time of erection. Some of the more important of these follow:

(1) Location of the school building in the proper relation to the general city plan and trends of population.

(2) Sufficient school grounds for adequate play space, light and ventilation covering possible future additions as well as present needs.

(3) Provision for future additions which will not interfere with good design, light and ventilation.

(4) Adequate lighting, fire resistive materials, etc., so that even if it becomes necessary at a later time to change room arrangements the general structure of the building need not be changed.

(5) Architectural design of simple, effective type.

Pupils to a Room

Thirty-three per cent of the rooms examined contained 40 or more pupils; 5 per cent contained 50 or more and several rooms were reported having from 70 to 100 pupils. The maximum limit of capacity of a class room should be 40, and 35 is a more desirable number. In school rooms containing more than 35 the individual attention which can be given to each pupil is not adequate for good results.

Out of 647 schools examined it is stated that in 571 attention is paid to the proper seating of pupils. It is impossible to gather from the data given in answer to the questions as to type of desks and seats how many are adjustable to the size of the pupil. Adjustable desks are essential. There are cases of crooked spine; stooped shoulders, and impaired circulation developing in the schools which must be stopped today to strengthen the future of the community.

Thirty-three buildings were found without natural, outside light in the corridors. In thirty-four other buildings some of the corridors had no outside light. Both health and safety demand that there be natural light in all corridors.

Out of 398 schools on which reports on stairways are made, only sixty-six have all the stairways enclosed in fire resistive material; 332 do not. Eighty-eight per cent of the schools have stair landings; and 85 per cent do not have sharp corners or obstructions on the stairways.

Twenty-three schools, or 5.5 per cent of all those examined as to lighting, have insufficient light in all rooms. In addition 442 rooms in various schools are reported to have insufficient light. Forty-six rooms have windows children must face. In eight schools all the rooms have cross lights and, in addition, in 641 rooms there are cross lights. When in a comparatively small number of schools—and these in the more progressive communities—so much unsatisfactory lighting exists, it is easy to imagine the damage being done yearly in the eyes of school children all over the country.

Approximately 23 per cent of the schools investigated were found to have unsatisfactory ventilation. Of the total number of 629 schools reporting on this question windows were used for ventilation in 203, artificial ventilation in 382, and both systems in 44.

Health Education

The means of providing proper ventilation in school rooms is a matter which is still under sharp discussion by experts. There can be no discussion, however, of the desirability of having a constant supply of fresh air in every class room. In some class rooms where school has been in session for two or three hours the odor is stifling. Can the effect be anything but detrimental to the health and mental alertness of our children?

The toilet rooms in 554 schools were found to be adequately lighted; those in 41 were not; five hundred thirty-five buildings were found to have adequate ventilation in the toilet rooms and 49 had not. Seventy-five per cent of the toilets were in the main building; 25 per cent in out-buildings. Of 603 schools examined, 470 use sanitary flush toilets; 108 sewer connected vault; 8 cesspool, and 17 privy.

Of the 160 cities making returns on health and physical education; ten

*Condensed from progress report on Surveys of School Buildings and Equipment, Health and Physical Education in the Schools made by Chambers of Commerce in cooperation with the Civic Development Department, Chamber of Commerce of the United States.

have a population of over 300,000; nineteen from 100,000 to 300,000; 26 from 50,000 to 100,000; twenty-three from 25,000 to 50,000; twenty-eight from 15,000 to 25,000; eighteen from 10,000 to 15,000; twenty-two from 5,000 to 10,000; and fourteen below 5,000. These cities represent forty-six states, the Philippine Islands, the District of Columbia, and Alaska. The total number of pupils in the elementary schools of these cities is 3,018,896.

In 62 of the 160 cities all the children are given a medical examination upon their admission to the schools. In 98 of the cities no such examination is given. The cities from 50,000 to 100,000 make the best showing, 61 per cent giving the medical examinations. The worst showing is by cities between 15,000 and 25,000, only 25 per cent giving examinations. The approximate percentage of cities of the other classes giving examinations is as follows: below 5,000, 29.5 per cent; between 5,000 and 10,000, 53 per cent; 25,000 to 50,000, 30½ per cent; 100,000 to 300,000, 37 per cent above 300,000, 33.3 per cent.

Many Schools Have Physicians

One hundred three of the cities included in this survey have school physicians and fifty-four do not. More than one third of the cities below 5,000 do not have school physicians, but in the classes above 5,000 the proportionate number of cities having physicians does not vary greatly.

About 9 per cent of the physicians employed in the schools of these cities are on full time and 91 per cent on part time. Ninety-three of the cities have dental clinics in the schools and sixty-six do not.

One hundred thirty-five of the cities have school nurses and 23 do not. The maximum number of pupils whom a nurse can look after with any degree of thoroughness is 3,000; two thousand is a much better number. The average number of pupils to each nurse in cities which employ only one nurse is 2,825 and in cities employing two or more 3,037. The greatest number of pupils to one nurse is 17,835 in a western city—the smallest number is 350 in a community of 1,977 in Pennsylvania.

A number of the cities which do not have school physicians have school nurses. Either nurses or physicians regularly inspect the children for defects or incipient illness in 132 of the 160 cities.

In 39 out of 160 cities no instruction is given in the care and use of

the eyes. In the other cities instructions are posted in the school buildings or studied in the class rooms. Rules for the proper use of the eyes have been prepared by the department of education in one state—these rules are posted in the class room or on the corridor bulletin board.

Forty-one cities report that they have open air schools or classes, and a number of other state that they will establish this system in the near future. The fresh-air movement in the schools is growing and its vital importance is more and more realized.

Supervised Play

In answer to the question, "Do the schools all have adequate playgrounds?" Ninety-one answer no, and sixty-eight yes. The smaller cities have of course the best showing. Of those under 5,000, 71 per cent report that all their playgrounds are adequate; those from 50,000 to 100,000 only 30 per cent have adequate grounds, and in those above 300,000 the percentage falls to 11. Fifty-four of the cities have no supervisor in charge of the play grounds.

In 102 of the cities scales are provided in all the elementary school buildings and in 56 they are not. Only thirty-four cities send home the child's weight record on the monthly report card.

Pupils can be interested in building up strong, well nourished bodies. They must, however, have the proper facilities so that they may note their progress.

Thirty-two of the cities provide a hot lunch or hot dish for each child in the elementary schools. Eight have milk available for all the children morning and afternoon; two provide it in the morning; 94 have milk available for the undernourished children.

The malnourished child is retarded physically and mentally so that he does not have a fair chance in life. A hurried breakfast and a cold "box-lunch" eaten at the school are not conducive to health building, and nutrition experts agree that the child should have milk in the middle of the morning, a hot lunch or hot dish with the lunch at noon, and if possible some nourishment in the middle of the afternoon.

In the public schools of 133 cities time is allowed each day for training the children in the establishment of proper health habits and in twenty-six no such training is given. This training includes tooth brush drills, breathing exercises, instruction in dietetics, personal hygiene, etc. One hundred forty-eight cities have a program of

general health education which reaches every child in the elementary schools and 11 do not.

The impression given by the reports from the cities examined (which are among the most progressive in the United States) is that although commendable progress has recently been made in bettering school conditions, we do not yet fully appreciate the fact that the health of the oncoming generations is a priceless asset to the community.

The most significant elements in the reports are these: (1) The increasing number of cities maintaining open air schools or classes thus salvaging imperfect human material and converting it to a high grade product. (2) The increasing number of cities providing milk for the undernourished school children. (3) The increasing number of cities providing a hot lunch or a hot dish for all the elementary school children.

Two facts which merit careful consideration are: (1) The absence of medical examination before children are admitted to the schools. (Less than 40 per cent of the communities take this essential precaution to safeguard the health of the community.) (2) The lack of adequate playgrounds where all the children can add to their store of health and strength. (Only 42 per cent of the cities claim adequate facilities.)

Other significant facts are these: Sixty-five per cent of the cities have school physicians; about 60 per cent have dental clinics; and about 85 per cent have school nurses.

The steady increase in dental clinics and school nurse systems in the past few years has been among the notable developments in American schools.

If the school health work is to function properly it is certain that there must be proper contact between the health officials and the parents. Evidently there is not such contact as only about 20 per cent of the schools send weight records home with the monthly reports.

The reports on buildings and equipment show us that not enough attention has been paid to erecting the type of building which will stand the test of years; that we are not giving our children a square deal in not protecting them from fire; and that many communities tolerate defects in the school building which make for impaired eyesight, weak lungs, and the spread of disease.

Among the elements being developed in the communities which have the most modern school systems are:

Properly planned buildings rightly located and surrounded by adequate open spaces; efficient health organization, including school physicians, den-

tists, and nurses; thorough medical examination of all children before admission to school; provisions for nourishment not only for malnourished but

for all elementary school children; outdoor classes and schools; and health instruction and supervised play.

Survey of Child Labor Conditions in Sugar Beet Fields

SUGAR beet farming produces an intensified crop requiring a large amount of hand labor, thus inviting extensive employment of children. Because of the control of the industry in comparatively few hands, with production and distribution on a factory basis, with contracts let out to farmers, payment on a piece-work basis and intimate direction of the work by supervisors and foremen engaged by the sugar companies, the sugar beet industry is in reality a factory industry, although its factories have neither roofs nor walls.

The purpose of a recent study of Child Labor in Michigan Sugar Beet Fields was to determine whether the work done by young children in the beet fields is detrimental to their health, their education, or their fitness for citizenship. With this end in view, a survey was made, not so much of the industry itself as of the relation of the industry to the employment of children. A synopsis of this investigation is contained in the March issue of *The American Child*.

The period of the survey was from May to November 25, 1922 when three agents of the National Child Labor Committee were in the field continuously except for the month of August. This field covered 12,804 acres in the "Thumb" and Saginaw Valley sections of Michigan, or about 20 per cent of its total acreage devoted to sugar beet cultivation.

The workers in beets consist of three classes: (1) farm owners who contract with the sugar companies to raise beets, and are called "growers," (2) farm renters who do the same, also called "growers," (3) contract labor families who engage to cultivate the beets for the first two. It is from the latter class that we get the "migratory" families, who follow the beet crop season after season, going into the fields when the season opens and remaining until the harvest. These families choose work in the beets for the reason that they may thereby find employment for their children in agriculture, which

is denied them by child labor laws prohibiting the labor of children under fourteen in factories or workshops. It likewise follows that preference in the matter of employment is given by

National Child Labor Committee
A girl of six pulling beets in Michigan.

growers to families of contract laborers who have large numbers of children, since there is a definite relation between the number of acres that can be cultivated and the number of children in the family.

The committee's agents visited 407 grower families and 274 contract labor families; also 115 schools attended by the children of these families from which were obtained attendance records of 5,581 children. Teachers in 53 other schools furnished the records of 1,444 other children of similar age for purposes of comparison.

In the 681 families visited there were 2,116 persons 5 to 20 years of age, inclusive, of whom 1,565 (73.9

per cent) worked in the beets. Of these, 1,358 (86 per cent) were children under 16 and over 5. Eight hundred were from contract labor families; 100 from families of renters; 458 from families of farm owners. The children under 16 at work in the beet fields comprised 49 per cent of the total number of available workers in these families.

Some of the labor necessary in the cultivation of beets is extremely arduous and the heavy knife used in "topping" is dangerous in the hands of unskilled children.

Owing to the shortness of the season and the danger of damage from frost, work is forced throughout the summer months regardless of weather conditions. Workers are in the fields by day-break and remain until dark, sheltering themselves as best they can from rain in summer and from sleet and snow in early fall.

Housing conditions among contract workers vary, but they are often of the poorest kind. Sanitary conditions are far from good and overcrowding is common. Some of the sugar companies provide company houses. These are sometimes on wagons so that they can be moved from field to field. The most common dwelling is the cheaply built shanty. In one instance a family of ten people lived in a one-room garage from May to October. A family of six lived in a tar-paper shanty located in a mud-hole.

Of the 894 children of the migrant families studied, eight hundred worked in beets.

Of the total of 1,358 children from all families under observation, 685 were found to be engaged in "blocking," "Thinning" and "weeding" follow almost immediately so that frequently a child worker and an older hand work together. Often a parent does the blocking while two children follow with the thinning. A total of 1,335 children were engaged at one time or another in "thinning," 1,336 in "pulling," and 1,286 in "topping."

The relationship of the number of

children in a family to the number of acres cultivated is definite. The 558 grower children helped to cultivate 2,252 acres and the 800 contract labor children worked 8,371 acres. That the number of acres a family can contract to work depends upon the number of children in the family, is shown by the following table, which includes all people under five years of age.

No. of persons in each family	Average number of acres of beets worked per family
2	14.3
3	19.4
4	24.1
5	26.8
6	31.4
7	37.7
8	45.3
9	47.2
10	68.3

Of the 5,581 children whose records were obtained from the local schools, 63.4 per cent lost time because of work either in beets or other forms of agricultural labor.

Nearly 70 per cent of all these child workers were in beets, Tuscola County leading with 79 per cent, the others ranging between 60 and 70 per cent.

The average school time lost was 23 per cent and of this, beet workers lost 82.4 per cent. Contract worker's children lost 63.6 per cent of their total school time; owner's and tenant farmer's children lost 29.5 per cent. Other forms of work were responsible for a loss of 21.5 per cent.

School in these regions is looked upon as an incidental luxury to be indulged only when there is no work to be done. The prevalent attitude of parents is that children should be an economic asset. "Why should I go to the expense of feeding and clothing my children and then when they get big enough to help, not get anything out of them?" asked one farmer, voicing really a prevailing opinion.

Among the migratory contract laborers this view is held even more strongly. They go to the country to work—not because it is more healthful but because they can use their children there at an earlier age than they can in city factories. Many families work in the beets only until the time when their children will be old enough to be put to work in the cities under the restrictions thus

possible under the child labor laws.

Much like this study just described is one on "Child Labor and the Work of Mothers in the Beet Fields of Colorado and Michigan," made by the U. S. Department of Labor through the Children's Bureau. The sections with which the report is concerned were chosen as representing two of the three principal beet-growing areas in the United States, the western mountain and the middle western area. In two Colorado counties 1,073 children under 16 years of age and 454 mothers, and in parts of three Michigan counties 763 children and 397 mothers doing beet-field work were included in the study. In each

were obtained worked from nine to thirteen hours daily.

Mothers working in the beet fields did so for long, regular hours, not merely at times when their household duties permitted; beet work took precedence over all other tasks. Meals were prepared and other housework performed at the expense of the mothers' sleep and rest. Many had small children but were able to give them very little care. Babies were usually taken to the fields, where they were in some cases sheltered by a tree or tent, but many fields were entirely without shade. Children 3, 4, and 5 years of age either played about the fields or were left at home, in many cases with no caretakers except other young children.

For the largest group of laborers' families in each area the season's earnings were from \$800 to \$1,000, while about half the Colorado families and less than one-third of those in Michigan earned \$1,000 or more. The value of a child's work, if he engaged in all the processes, averaged about \$200 in Colo-

rado and among the Michigan children, who were less experienced, from \$114 to \$122. It is estimated that the former, on an average, cared for 5.9 acres per child and the latter, 4.1 acres per child.

Free Vaccination Service in Montevideo

Free vaccination service for children of Montevideo (Uruguay) public schools is supplied through the dental clinics in conformity with a resolution of the Board of Education by which no child will be admitted to the schools without presenting a vaccination certificate.

Better Homes Week, observed June 4 to 10, gave thousands of persons throughout the country objective demonstration of the last word in household management and construction. Everything for the home which includes practically everything produced by the manufacturing world, was displayed in a manner calculated to induce better sanitary and health conditions in the home, and more leisure through better household administration.

A one-room shack with two partitions that houses ten persons in the Michigan sugar beet field.

section four-fifths of the working children were less than fourteen years of age and one-fourth were less than ten. A large proportion of the six and seven year old children in the families interviewed and three-fifths of the eight year olds had done beet-field work. A mother quoted as describing a common custom said that her child had worked "ever since he could lift a beet."

The work is described as unsuitable for children because of its monotonous, uneducative character, its interference with schooling, and the long hours involved in the rush work at certain seasons. During the thinning process which must be completed before the plants grow too large, 85 per cent of the Colorado children included in this study and 67 per cent of those in Michigan worked from nine to fourteen hours a day. Two-thirds of the children in each section who engaged in hoeing had a working day of 9 hours, or longer, and at harvest time, in order to get in the crop before it was caught by a heavy frost or otherwise spoiled, three-fourths of those for whom hours

A French Medical Examination Center Plan

THE province of Seine-Inférieure in France has organized a peculiarly significant chain of dispensaries with a visiting nurse staff, a preventorium for 250 children, a hospital, sanatorium, milk station, and the like. The following description of the health center plan involved in this program is taken from the first number of the first volume of the new journal, *Annales d'Hygiène Publique, Industrielle et Sociale*, which takes the place so far as public health work is concerned of the old *Annales d'Hygiène Publique et de Médecine légale*.

The public health department of Seine-Inférieure acts through the medium of organizations called medical examination centers, established in every locality where the density of population would lead one to anticipate a development of social diseases in the neighborhood. The term "medical examination center" has been substituted for the usual name of dispensary to avoid confusion and to establish the principle that the center is not to give continuous medical care, which is reserved to the family physician, but to provide advice in regard to individual prophylaxis and public health. It is a center for the detection of social diseases and for the hygienic education of the people. It is open to everyone who presents himself. Practising physicians have free access to it and may obtain the benefit for patients of limited means of all the methods of investigation and examination at the disposal of the center.

The role of the medical examination centers is defined as follows by Article 4 of the regulations of the department:

The medical examination centers approved by the department shall provide:

(1) Advice in regard to hygiene and prophylaxis to all persons who present themselves or who are re-

ferred to it by their physicians.

(2) Loans of prophylactic material.

(3) The education in prophylaxis of the families of the sick through the means of specialized personnel working under the direction of the physician of the center and placed at the disposition of all practising physicians who may require it.

(4) The benefit of the various laws in regard to aid to be furnished to all sick people and the families of the sick corresponding to the provisions established by law and regulation.

(5) Such technical examinations as

of the skin and mucous membranes.

(3) Medical supervision of maternity.

(4) Medical supervision of infants.

(5) Medical supervision of school children. These different sections are installed in the same building wherever it is physically possible to do so. In the large cities on account of material exigencies this may not be possible.

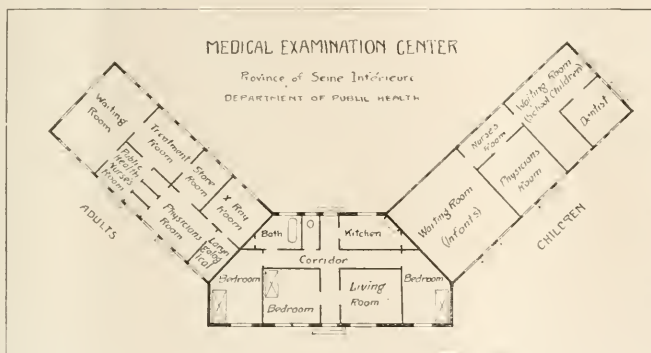

The medical examination centers tend always to approach the typical plan here presented, to be modified in details, adapted to local circumstances and realized bit by bit according to

local necessities and the resources of the moment. Each medical examination center includes in principle three entirely distinct and separate wings:

(1) A wing reserved for adults including a waiting room, the office of a public health nurse where every sick person or visitor is questioned in

privacy and may talk confidentially to the nurse who serves as the invaluable assistant of the physician; the medical office with its necessary adjuncts, the laryngological room, the radiology room and the like. The sick person here finds himself alone with his medical adviser protected from miscellaneous contacts or publicity; two small dressing rooms for the preservation of decency are interposed between the office of the nurse and that of the physician.

(2) A wing exclusively reserved for small infants, and including a waiting room provided with individual hammocks for each infant, where is carried on the collective education of the mothers by short talks given by the physician of the center; the office of the nurse; and the office of the physician; where every child is weighed, measured and examined in the presence of the mother who receives from the physician special advice supplementing the general advice already received.

may be demanded by practising physicians or recognized as useful by the physician in charge of the center.

(6) Various services of disinfection and sanitation in cooperation with the established health authorities.

(7) The distribution of various materials to individuals in need, or to members of the association established under Article 7 of the law of 1916.

(8) In addition to its usual services, and in very exceptional cases, the giving of medical care in emergencies and while awaiting the intervention of the family physician. In principle such care is reserved for the indigent and members of associations organized under Article 7 of the law of 1916. In no case shall the examination center provide directly for the continued treatment of the sick, which is always reserved for the family physician.

To reach the whole group of social diseases each medical examination center shall include five sections dealing respectively with: (1) Affections of the respiratory tract. (2) Diseases

(3) A wing reserved for the nurses.

Through the organization of its five sections the medical examination center takes the infant from its prena-

tal period, brings its gestation to a successful end and conducts it always under medical supervision, up to the end of the school period. In parallel to this medical supervision of the in-

fant, sections 1 and 2 take charge of the parents themselves so as to neutralize in them the disastrous effects of such of the social maladies as are most directly accessible.

The Cost Account of Public Health

Real Accounting Calls for Credits As Well As Debits

THE feelings of Dr. Fred Converse, county health officer, had been ruffled that morning. Bob Cator, the village gossip, had told him that Jackson Holly, a farmer whose place was near by, had been denouncing him. "He says," went on Bob; "that you and that nurse, Miss Gordon, are nice folks but that it ain't fair to tax hardworking farmers to let you lie round and do nothing."

Dr. Converse had blinked; but had answered laughingly. "Holly's a good man," he agreed. "He speaks right out and gives you a chance to answer him. If you see him before I do, Bob; you ask him to drop into my office some day with his account book, and I'll try to astonish him."

An hour later, when the doctor reached his office, he went over his records to see just what the county health service had done for Mr. Holly; and he was amazed. "Great Scot," he exclaimed. "I knew our health work came cheap; but I never dreamed that—"

He broke off as his office door opened and jumped up to welcome Mr. Holly and half a dozen others who came in, piloted by Bob Cator, who had plainly lost no time in doing as the doctor has asked.

When they were seated Mr. Holly cleared his throat. "Got your message, Doc," he said; "and came right around. Brought some folks with me as umpires!"

"Great!" Dr. Converse was delighted. His visitors were among the most influential in the country; and he had long hoped to get a chance to talk to them. "I'm mighty glad to see you all. I see you've got your account book, Mr. Holly . . . Now if Bob Cator will keep score on the blackboard—Thank you, Bob!"

"Now, Mr. Holly," went on the doctor. "Let's begin by seeing what the county health service really costs you. What health tax do you pay?"

"Pay twenty-two cents per one thousand dollars valuation. My valuation's eight thousand dollars; makes my health tax \$1.76 a year. Don't

seem much to city folks, maybe; but it's only one thing out of a lot; and it all counts up when a man's got to earn his living in the blazing sun."

"Quite true. And whether it's much or little you're entitled to know what it's spent for" . . . "Bob! Put down 'Cost' on the board and below it write Health Tax—\$1.76. Any other costs, Mr. Holly?"

"Lots of them." Mr. Holly opened his account book. "Here's the cost of those danged window screens you fellows persuaded the County to make us buy to keep out mosquitoes and that weren't a darned bit of use to us. That's an expense; all right! Course you fellows didn't get the money yourselves, but—"

"All right. What did your screens cost?"

"Fourteen dollars and twenty-four cents. That's for the house and for the annex where the farm help lived."

"All right! Put it down, Bob! To health investment \$14.25. Of course, Mr. Holly; you know the country spent as much more in oiling and draining the ponds where the mosquitoes breed. That's something you got for your health tax. But never mind! Tell me: How much did you spend for malaria sickness—medicines and doctor's bills—for the twelve months before you put in the screens?"

Mr. Holly thumbed his book. "Bout twenty dollars for doctoring and two dollars for quinin," he decided.

"All right. Now how much have you paid for the same things during each of the two years' since you put the screens in. It's been just about two years, hasn't it?"

"Ye-es. I reckon so. But—" Mr. Holly frowned and searched his book. "Paid mighty little," he admitted. "We aint had any malaria worth speaking about these two years. The mosquitoes just didn't come 'round. And so, of course, the screens didn't do us a bit of good."

"Didn't they? The mosquitoes came around all right in Alta County, right next door; didn't they?"

"Well—maybe they did, the first year, anyhow! Last year they didn't come anything to speak of."

"Wasn't that because Alta County screened and oiled and drained a year later than this county did? Isn't it fair to estimate that you would have had to pay at least another twenty-two dollars each year if you hadn't put in those screens. Alta county people paid at least that much. Seems to me that your health investment of \$14.25 has saved you two times twenty-two dollars, forty-four or \$29.75 net. And you've got your screens still. Shall we ask Bob to write down: Profit \$29.75?"

Holly hesitated. But the umpires chuckled and he agreed hastily. "Yes! Put her down, Doc," he said. "Guess that's all about those screens, aint it?"

"Not quite. How many days work did you and your men lose from malaria in the year before you put in the screens?"

Mr. Holly frowned. "Oh! Five or six days, maybe," he said. "But what's that got to do with it?"

"Everything. You paid the men, didn't you; and lost five or six days because they were too sick to work; so you lost the money. And you were down with malaria yourself that summer, weren't you? Lost some time didn't you? And even when you and the men were better, you weren't up to par so you could do a real full day's work, were you? And in the next two years you didn't lose anything like so much—from malaria? The screens, etc., saved you the difference between what you lost in each of the last two years."

Holly scratched his head. "Well, if you want to count that, I s'pose you've got a right to do it," he said. "Say, Bob! I reckon you'd better chalk down about twenty-five dollars profit from saved wages due to those blamed screens. Now, what's next, Doctor?"

"Smallpox!"

"Smallpox? There aint been any smallpox here since I came, except of course what that Stone family

brought when they refugeeed here from the west end of the state and sent their two children to school till they broke out with it two days later. But it didn't spread?"

"Why didn't it spread?"

"Well! I don't know. I don't hold much with vaccination; but I reckon it was because most everybody here, especially the school children, got vaccinated right away. But what—"

"Who vaccinated your family?"

Holly hesitated. "Well," he said; finally, "Mandy—Mandy's my wife, you know—Mandy went wild when she heard about the Stone children and she grabbed two of our children, all she could get her hands on right then, and rushed them to Dr. Morford's and had him vaccinate them. If she'd waited half an hour we could have brought them to you and got the six of us fixed up for nothing." Holly turned resignedly to the blackboard. "Bob!" he said. "Enter up \$4 to saving on vaccinations."

The umpires applauded freely; and Mr. Holly joined in, though somewhat ruefully.

Then Dr. Converse resumed. "Now about the public health nurse," he remarked. "Being a mere man, Mr. Holly; you probably don't remember how many visits Miss Gordon made to your place the first year you were here. But I see Mrs. Cator at the back of the room; and I'll ask her to tell us all about Miss Gordon's visits to her when her baby was born last spring and when her other girl was ill the fall before that. How much were those visits worth, Mrs. Cator?"

Mrs. Cator stood up. Twice she tried to speak before the words came. Then—

"I don't know," she burst out. "You ask Bob Cator how much his wife and children are worth to him. That'll be just what those visits were worth. I aint saying anything against Dr. Morford; he's a mighty good doctor, I reckon. But he's just a man, and I lived a long way from everywhere and—and—My God! When I remember that time—it was Miss Gordon's coming that pulled us through. It was having another woman around—a woman that *knew* what to do and that did it without making any fuss about it. And—and—" Mrs. Cator swung around to her husband. "Bob Cator; if you been saying anything against Miss Gordon, or against Dr. Converse either, I'll—I'll—" Helplessly she dropped into her chair.

When the umpires had gotten over their somewhat chucky and hysterical laughter, Dr. Converse resumed.

"I'll come back to health nursing after a little," he promised. "But just now I want to take up another subject." He turned to Holly. "Mr. Holly," he said, "I hope I won't offend you by what I'm going to ask. You'll understand why I do it after a little while. Won't you tell us how your children stood at school the first year after you came here?"

Mr. Holly flushed hotly. "Get offended?" he exclaimed. "No! I won't get offended. But I'm hurt a lot. It wasn't the fault of those little tykes that they didn't stand high. All four them was sick when we come down here; and it wasn't to be expected that they'd do much—"

"Exactly. Where you came from you didn't have any malaria problem. And unless you wished you didn't have to put in any screens to keep out the flies that carried filth on their feet. Two of your children had typhoid fever in Tunlaw County, didn't they? Got it from flies or from an infected well, probably. None of them had it down here, did they? Do you know why? It was because I, as health officer, made Jones, who sold you the farm, fill in his well because it was a cesspool of pollution and dysentery and typhoid that had cost him the lives of his wife and his only child. I made him dig another in a better place by threatening to prevent his selling his farm to anybody until he did. That's why you haven't had any bills to pay for typhoid or dysentery or maybe for funerals. Those mosquito screens that keep out flies and the sanitary privy that kept the flies from getting pollution on their feet to be carried to your food saved your family. Can you calculate how much all this service was worth to you?"

Mr. Holly shook his head. "No, I can't," he admitted. "But I know it's worth a lot."

"Then try to calculate this: When you came here your two eldest boys had hookworm disease; they probably got it when they visited their uncle down in the hookworm belt. One of them and your girl had adenoids that were deforming their faces and interfering with their breathing and thinking. Your girl also had a cataract that made her so deaf that she couldn't hear half the teacher said; and so she got the credit for being dull and stupid—"

"Dang you!" Holly was on his feet. "Maybe that's true, but I aint going to listen to any more of it. I just—"

"Then listen to this Mr. Holly. Why is it that your children are now among the brightest and healthiest and

finest children in the school? I'll tell you why. It's because the county health service cured the two that had hookworm and gave them a chance to get well and strong. And it's because Miss Gordon nearly wore herself out going to your house the first winter you were here and urging Mrs. Holly to persuade you to have the adenoids that were ruining two of your children taken out at our nose and throat clinic; and persuading you direct to take darling little May to town to a surgeon to have her hearing attended to. She isn't considered stupid now, is she? I'll tell the world she isn't. Consider what those children are now and what they were then; and tell me what the county health service has done for you that's worth while."

"Done for me?" Holly was on his feet once more. "It's done everything for me. It's made me attend to things that I was too big a fool to attend to of my own accord. It's sent you here to give me advice for—for—Good Lord—for \$1.76 a year. Think of it: \$1.76 a year. It's given my boys health and strength and a chance to be something. And it's given me back my little May as bright and rosy as she was when she was a baby. Doctor! You needn't calculate any more. Just charge me up with a million dollars worth of health—price \$1.76."—
Issued by the U. S. P. H. S.

Kansas Now Has Commission for Blind

Kansas has passed a law creating a commission for the blind, the functions of the commission to include, along with the usual provisions, co-operation with local and state agencies in all activities looking toward the prevention of blindness, especially in the dissemination of especially prepared literature on the hygiene of the eyes.

Competition of frozen meat from South American packing centers has become so serious to the Australian frozen meat trade as to encourage the utilization of beef cattle in Australia and New Zealand for the production of meat flour which is made as successfully as dried milk in this country. Drying and pressing eliminate around 60 per cent of the moisture. The separated fats and juices are then returned to the meat, which is further dried preparatory to reduction to the consistency of meal. The meal contains unredressed the nutritional properties of the meat and can be preserved indefinitely, says *The Chemical Age*.

School Heating and Ventilating

EVER since mechanical equipment was first installed as a means for the precise control of air conditions in public places the public school has been a favorite field for experimentation in ventilation and, it must be admitted, for the exploitation of more or less radical ideas. In the main, however, apparatus only that is fundamentally sound has persisted and, by a gradual process of elimination, the best is in general use.

It is to be noted, however, that no "system" assures good ventilation. Ventilating practice is nowhere better than the intelligence accorded the subject of air control and—it might well be added—the intelligence of the public so served. The whole matter of heating and ventilating systems for schools was discussed in a recent issue of the *National School Building Journal* by C. A. Booth, of Buffalo.

By mechanical ventilation, he says, we mean the use of fans and other apparatus for the purpose of air conditioning—and it may be well here to state that the term "air conditioning" covers nothing more complicated than the producing of such conditions of air cleanliness, temperature, and moisture, as may prove most desirable. For a textile mill, or for a bakery, air conditioning means something quite different than for a public building. At its best, it means for a school more than simply heating or ventilating, and yet the means of insuring properly conditioned air are simple, and the results certain. The fan, the air washer, the radiation surface, the air ducts and dampers, the thermostats for regulating temperature, the low pressure boiler with its auxiliaries, are the prime and practically the only requisites for such a system, and the results depend more on a capable and conscientious janitor than on any high degree of technical operating skill.

Thirty years ago the hot air furnace was in common use for schools and other buildings for which ventilation was supposed to be essential. The furnace system had the advantage of a low first cost, but even in those days of cheap fuel its operating expense was considered too great. The amount of fuel required was much more than for the steam hot blast system, the ventilation conditions obtained with the latter were better, and the hot air furnace has survived only in a few localities in the northern states. In the southern states mechanical ventilation has been given very little attention, largely, of course, on account of the less severe climate, and the fact that the total

investment for schools is much smaller.

The steam hot blast system has come then into general use, but in the course of time it has, and still is, going through many modifications. The arrangement most favored by architects and heating and ventilating engineers twenty years ago was what is known as a straight hot blast system. In this system all air for ventilation

originally intended as a measure of economy to permit the heating of the building outside of school hours without operating the ventilating system, it had a tendency to result in unnecessary duplication and expense. For example, it has not been uncommon to see school buildings with the split system in which almost the full heating requirement could be taken care of by either the direct radiation, or by the ventilating apparatus. Even if this excess capacity did not exist, the duplication of the two systems was in itself expensive; the most serious objection, however, came from the virtual divorcement of the ventilating system from the heating.

Even with the best supervision it was hard to be certain that the ventilating apparatus was in constant operation during school hours. Engineers and janitors were naturally averse to doubling their coal consumption and their labor for a result which was not tangible and, unfortunately, proper supervision over operating conditions of ventilating plants in schools is the exception rather than the rule. Above all, there was good cause for consternation, with mounting fuel costs, at the cost of securing ventilation.

I mentioned previously that ventilation plus heating doubled the fuel cost as compared with heating alone. As a matter of fact, under the conditions obtaining in most of our northern schools, the use of outdoor air for ventilation places a load on the heating plant of nearly three times as much as the heating requirements for a well constructed school building. In one of our northern winters this fact is one for serious consideration.

In view of the tendency on the one hand to increased first cost by duplication of apparatus, and, on the other hand to increased first cost by dupli-expense for fuel, it is no wonder that leaders of the medical and engineering professions began to question just where this tendency was leading. The standard for good ventilation has been considered as thirty cubic feet of fresh air per minute per occupant, but as the lung capacity or, in other words, the amount of air inhaled and exhaled in the same time, is but a

very small percentage of that amount, about one-third of a cubic foot, it is understood that the thirty cubic foot standard is to be regarded only as a coefficient of dilution. It is also well known that exhaled air contains no poisons or injurious elements, somewhat contrary to the popular belief, and that the carbon dioxide content, which had been the customary measure of impurities, also had little significance, since carbon dioxide, even in a concentration considerably greater than usually found, is entirely harmless. As a matter of fact, the infiltration through the walls and around the

DR. HERMAN M. BIGGS IS TAKEN

Dr. Herman M. Biggs, state health commissioner of New York since 1913, died in New York City on June 28. The health achievements loom large that can be attributed directly to the efforts of Dr. Biggs. Their ultimate value it is impossible to estimate. His death is a distinct loss to health work generally, but the vision and personality of the man will long permeate the cause to which his life was devoted.

was taken from outdoors, and no direct radiation was used, except in toilets, corridors, etc., the class-rooms being heated as well as ventilated by the incoming air, which was warmed by passing over sufficient indirect surface to take care of the heating requirements.

Later what is known as the split system was introduced, with the practice of heating the class-rooms wholly or in part by direct radiation, and using only enough indirect heating surface to bring the incoming fresh air up to or a little above the room temperature of 70 degrees. While

windows is much greater than the amount of air which is actually breathed into the lungs of the occupants of the average school room.

Experiments at Wesleyan University, at Johns Hopkins, and within the last year at the Research Bureau of the American Society of Heating and Ventilating Engineers, have brought to light much additional information on the so-called zone of comfort. From these experiments it appears that the wet bulb temperature is a better indication of comfort than the dry bulb, which confirms previous and somewhat less accurate data to the effect that humidity is of quite as much importance as temperature in producing proper and comfortable air conditions. A room temperature of about 65 degrees to 68 degrees, with a wet bulb temperature of 50 degrees, and a slight sensation of air in motion, have been pretty definitely determined to be not only the conditions most conducive to comfort, but most favorable for the heart, respiration, and all bodily functions. These experiments, it may be added, have been conducted under the most scientific conditions, and have been repeated so many times, and by so many different experimenters, that the results can hardly be questioned.

These results have been a marked confirmation of the wisdom of the system which has come into common use in various sections of the country, notably throughout Minnesota, Wisconsin, and Iowa, and in the schools of St. Louis and many other large cities; this is referred to as the recirculating system, and has for its most prominent feature the recirculation during school hours of approximately seventy-five per cent of the air supplied for ventilation. I will first outline the features of the mechanical equipment, and then mention the results obtained.

Ventilating fans of the modern multiblade type, usually motor driven, are used with a spray type air washer having provision for keeping the eliminator plates covered by a film of water, so as to accomplish complete dust removal without materially adding to the humidity. The air washer ordinarily recirculates the water from the settling tank, but this water is changed twice a week, or oftener, if conditions require. The indirect radiation is sufficient to heat all rooms for which ventilating air is supplied. Direct radiation is provided only in the unventilated spaces, or those rooms which have gravity exhaust ventilation, such as toilets. Only enough heating surface is installed to heat the building when three-fourths of the air handled is recirculated and one-fourth fresh air taken from outdoors. Automatic temperature regulation and a simple automatic humidity control regulate the wet bulb as well as the dry bulb temperature in the rooms; the thirty cubic feet per minute per occupant, for which provision is still made, creates a sensation of the air in motion, and it is possible to increase or to decrease this volume of air without very materially affecting the cost of operation.

What, then, are the results? First and foremost we have the assurance

of a system in operation, instead of an expensive ventilating equipment which is lying idle, permitting unhealthful conditions, while the impression exists, even no doubt among the members of the school board, that everything has been done to provide for the welfare of the children. The ventilation is no longer divorced from heating, but goes hand in hand, and its operation is compulsory.

The air is conditioned in accordance with the best present standards, on which the authorities are in closer agreement at this time than ever before. According to these standards, overheating is the most undesirable

condition; air free from dust, in moderate motion, and with a predetermined degree of moisture must be supplied. With such a system the windows may be opened if desired, no unbalancing or uneven distribution of air will result, and the effect of the open windows will be felt nowhere except in the same room. Not by any means the least important consideration is the fact that with such a system the reduction in fuel cost is at least 50 per cent as compared with using outdoor air for ventilation. Air recirculation has been practiced successfully for too many years to be considered in any sense an experiment.

CLEANING AND DYEING INDUSTRIES

The plant of a cleaning and dyeing establishment at La Grange, Ill., where local ventilation, adapted to the special condition to be corrected, takes equally good care of fire and health hazards. Fire hazard affects the point at the left of the picture, while heat and humidity are countered at the right.

Anilin poisoning in black dyeing has been the subject of several recent investigations. Comparisons between the dangers of steam processing and the oxidation process have been reported recently by Raymond Williamson in the *Journal of Industrial Hygiene*. The relation between anilin poisoning and the hours worked per week was very definite. Two other factors were very definitely developed by the study: The application of local ventilation in the various parts of each process, and the separation of the various parts of the process in different rooms. It was held that the atmosphere in all works where anilin is used contains a certain amount of vapor which is productive of different degrees of anemia and symptoms of anilin poisoning. Individual susceptibility plays a part in the picture, but local ventilation is in any case held to be essential.

In cleaning establishments the fire hazard is added to the health risk, and the humidity of pressing rooms contributes its share in the deterioration of the worker. Modern methods of air control make possible the hygienic air conditions which in these

industries mean preservation of health to the worker.

Cooperative Scheme for Officing In Chicago

Announcement is made that twelve of the leading social agencies of Chicago have undertaken a scheme of cooperative officing in the Keehn Building, 308 North Michigan Avenue. Economy in cost of space is fostered by the plan, supplies are secured cheaper through joint purchasing, and administrative efficiency is promoted through organization of common services. The organizations concerned are: Chicago Association for the Prevention and Relief of Heart Disease, Chicago Council of Social Agencies, Glenwood Manual Training School, Illinois Children's Home and Aid Society, Illinois League of Women Voters, Illinois Society for Mental Hygiene, Illinois Society for the Prevention of Blindness, Infant Welfare Society, Joint Service Bureau, Religious Education Association, United Charities of Chicago, and the National Board of the Young Women's Christian Association (Chicago office).

Lighting Code for Massachusetts Industries

THE following code for lighting industrial establishments has been adopted by the department of labor and industries for the purpose of protecting employees from accidents and eye strain due to inadequate or faulty lighting.

This action has been taken under authority of General Laws, Chapter 149, Section 6, which requires the department of labor and industries to "make reasonable rules, regulations, and orders applicable to either employers or employees or both for the prevention of accidents and the prevention of industrial or occupational diseases," and Section 113, which provides that "every factory, workshop, manufacturing, mechanical and mercantile establishment shall be well lighted, well ventilated and kept clean and free from unsanitary conditions, according to reasonable rules and regulations adopted by the Department with reference thereto."

The requirements presented represent the minimum standard to be maintained for this purpose, and are to become effective January 1, 1924.

In preparing this code, the department was assisted by the following committee:

Dr. Louis Bell, chairman, Federal Committee on Lighting, Boston; Dr. Walter B. Lancaster, oculist, Harvard Medical School, and Massachusetts Charitable Eye and Ear Infirmary, Boston; Dr. Harry Linenthal, physician to out-patients, Massachusetts General Hospital, Boston; Dr. Wade Wright, director, Industrial Clinic, Massachusetts General Hospital, Boston; Dr. Frederick H. Verhoeff, oculist, Harvard Medical School and Massachusetts Charitable Eye and Ear Infirmary, Boston; Edward M. Coffin, staff engineer, Associated Industries, Boston; Charles F. Horan, director of safety, Hood Rubber Company, Watertown; John Newington, expert on lighting for New Bedford Cotton Manufacturers' Association, New Bedford; P. Harry Jennings, business agent, Boston Central Labor Union, Boston; Leonard W. E. Kimball, representative of Electrical Workers' Union, No. 103, Boston; and S. E. Whiting, assistant engineer, Liberty Mutual Insurance Company, Boston.

The assistant commissioner sat with

the committee, representing the department of labor and industries.

Part I—Rules

Rule I.—General Requirements. (a) Working or traversed spaces in buildings or grounds, and all working places during the time of use, shall be supplied with light in accordance with the following rules. (b) The location at which the principal illumination is required is herein expressed as "at the work." Measurement of the illumination shall be made at this location in the usual plane in which the work is done; that is, on a horizontal, vertical, or intermediate plane, as the case may be. (c) For the purpose of light measurements, a standardized photometer shall be used and such measurements shall be made at such locations specified in the tables.

	Minimum
Foot-Candles at the Floor Level, Required	
1. Roadways and yard thoroughfares	0.02
2. Storage spaces	0.25
3. Exits, passageways, stairways, hallways, elevator entrances, elevator cars, dressing rooms, washrooms, toilet rooms, water closet compartments ..	0.50
Foot-Candles at the Work	
4. Work not requiring discrimination of detail such as handling material of a coarse nature and performing operations not requiring close visual application	0.50
5. Rough work requiring discrimination of detail, also work in basements of mercantile establishments requiring discrimination of detail	1.00
6. Rough work requiring closer discrimination of detail, also work in basements of mercantile establishments requiring closer discrimination of detail, intermediate between 5 and 7	2.00
7. Fine work, such as fine lathe work, patterns and tool making, also office work, such as accounting and typewriting ..	3.00
8. Fine work, requiring closer discrimination of detail, such as watchmaking, engraving and drafting	5.00

Rule II.—Intensity Required. The minimum intensity of illumination to be provided and maintained is given in the following tables:—

Rule III.—Protection from Glare; Shading of Lamps. Lamps producing glare in the ordinary field of vision from any position at which work is performed, or such lamps located in traversed spaces in buildings, shall be provided with shades, reflectors, diffusing glassware or other accessories, installed and arranged in such manner as to minimize glare.

Such devices shall be of substantial construction and made of non-inflammable material; the term "non-inflammable material" as used in this rule shall mean material which will not readily ignite or burn. The term

"minimize" as used in this rule shall mean to reduce to the smallest practical proportion."

This rule shall not apply to lamps for a temporary decorative purpose where an unusual or harmful glare is not created.

Rule IV.—Distribution of Light. Lamps shall be so installed with regard to height and location, spacing, shades, reflectors, and other accessories as to secure a good distribution of light on the work and avoid objectionable shadows and excessively sharp contrasts.

Rule V.—Entrance and Exit Lighting. Lighting shall be provided in all stairways and exits of factories and in the passageways appurtenant thereto, independent of the regular lighting of the working space. The lighting circuits for the stairways and exits should extend inside any working room where 20 or more persons are regularly employed, so as to light the immediate entrance to the stairway or exit. Such lights shall be served from a source not subject to failure because of the failure of the circuit fuses for the room lighting, and preferably from an independent connection extending back to the main service entrance for the building. In case unusual danger may exist on account of type of building, nature of the work, crowded conditions, or lack of suitable exit space, the Commissioner of Labor and Industries may require such lighting to be further extended within the working space; and that independent service shall be insured by connection to a separate source of supply without or within the building.

Rule VI.—Classification. Assignment of industrial operations to Grades 1 to 8 inclusive, of Rule 2, shall be determined by the commissioner of labor and industries subject to review by the department upon application of anyone affected thereby.

These rules may be modified in whole or in part, with respect to existing installations by the Department of Labor and Industries on the showing of adequate reason for such action at a hearing when all interested parties are given an opportunity to be represented.

Under the provisions of the statute, any person who violates any reasonable rule or regulation, order or requirement made by the Department of Labor and Industries is subject to a fine of not more than \$100. (*General Laws, Chapter 149, Section 180.*)

Part 2—Recommendations

To reach at all times the mandatory values required in Rule II, the initial illumination, when the equipment is installed, should exceed those values by at least 25 per cent.

The intensity requirements for adequate day lighting are much higher than those for adequate night light-

ing, because under daylight conditions the brightness of objects in the field of vision is generally much greater than at night, and hence for good visibility, a correspondingly more intense light must fall on the object viewed.

The darkest part of any working space, should, under normal daylight conditions, be illuminated by natural light, to not less than the intensities specified in Rule II. It is recommended that the minimum intensities of natural light should considerably exceed those specified for artificial light in Rule II.

When part daylight and part artificial light are used, a higher intensity is usually required than for artificial light alone.

The minimum requirements in Rule II specify the lowest illumination with which employees can properly be safeguarded against accidents and eye strain. The illumination in well lighted factories is much higher than this. The intensities for desirable illumination are given in the following tables.

Foot-Candles at the Floor Level.	Modern.	Practic.
1. Roadways and yard thoroughfares	0.05 to 0.25	
2. Storage spaces, aisles and passageways (other than exits)	0.50 to 1.00	
3. Exits, passageways, connected therewith, stairways, hallways, elevator entrances, elevator cars, dressing rooms, wash-rooms, toilet rooms, water closet compartments	1.00 to 2.00	
4. Work not requiring discrimination of detail.	1.00 to 2.00	
5. Rough work requiring discrimination of detail	2.00 to 4.00	
6. Rough work requiring closer discrimination of detail	4.00 to 6.00	
7. Fine work	6.00 to 8.00	
8. Special cases of fine work	8.00 to 15.00	

The foot-candle, the common unit of illumination, is the lighting effect produced upon an object by a standard candle at a distance of one foot; at two feet the effect would not be one-half foot-candle, but one-fourth foot-candle. A lamp of twenty-five candle power in every direction would produce an illumination of one foot-candle at a distance of five feet in any direction.

In all cases in which work must be performed under very low illumination, such as hardening steel and certain glass processes, safeguards against accidents should be provided.

Where steam or smoke is occasionally present, such as in dye houses and on molding floors of foundries, similar safeguards should be provided.

Certain operations—for example, photographic processes, are carried out in darkness, but spaces so used must be provided with available lighting for use in emergencies.

Emergency lighting when required should have a minimum intensity of one-half foot-candles.

Glare may be defined as any brightness within the field of vision of such a character as to cause discomfort, annoyance, interference with vision or eye fatigue.

Serious glare may result from specular reflection from polished and other materials upon which work is being performed. It is sometimes practicable to avoid such glare by a change in the relative location of the light source and the work, but usually it can be obviated successfully only by decreasing the brightness of the light source.

Glare resulting from contrasts will be more serious in the case of dark walls and ceilings than where these are painted a light color.

The most common and troublesome cases of glare are those which are due to unshaded or inadequately shaded lamps of high brilliancy and candle power near the eye within the field of vision.

Protection from Glare.—Lighting, whether natural or artificial, should be such as to minimize glare, and prevent discomfort or injury to the eyes.

Shading of Lamps.—Shades for lamps should be either opaque, translucent, or diffusive, and of such a nature as to give good distribution of light.

The ordinary vacuum type incandescent lamp, especially in the 50 watt size or less, is usually not a serious source of glare unless located too near the eye in the field of vision; however, shading of these lamps where feasible is desirable, as it should add materially to the effectiveness of the illumination. Since gas-filled electric lamps and incandescent mantle gas lamps usually have a much greater brilliancy and volume of light, they should not be used in the normal field of vision without adequate shading.

Shading of Windows.—Shades or awnings or other suitable devices should be used to minimize glare wherever the location of the work is such that the workers must face large window areas through which excessively bright light may at times enter the building.

The saw-tooth sky-windows of modern factory construction permit an adequate and nearly uniform daylight illumination of the floor area, and are desirable when practicable. When rooms are illuminated through side windows, it may sometimes be advisable in order to prevent glare, to use prismatic glass in the upper sashes of the windows.

Switches and controls should be so placed that at least pilot or night lights, which may form part of the entrance and exit lighting, may be lighted, if not kept regularly burning, from main point of entrance for employees. Such controls should be plainly labeled.

All lighting equipment should be cleaned and kept in order so that the intensities of illumination never fall below the minimum requirements.

The light from lamps and windows is frequently reduced twenty per cent or more through ordinary accumulation of dust and dirt; therefore, the value of care and regular cleaning is obvious.

A League for Mental Hygiene, modeled on and affiliated with the League of Mental Hygiene of North America, has been formed by the Brazilian Psychiatric Society.

Results of Swedish Eight-Hour Day Studied

The Swedish Office of Social Affairs has completed an investigation into the social and economic effects of the provisional legislation reducing hours of work, in force since 1920, says a statement from the National Industrial Conference Board. Though lacking any exact statistical statement of the economic results of the application of the act, reports to the board indicate that the employers' usual estimates of an average increase of 15 to 20 per cent in the cost of production are in general too high.

"A special inquiry made by the Board of Trade throws some light on this point," the statement says. "Local investigations were conducted by experts in some forty undertakings in different branches of industry. These undertakings were divided into two groups—those which increased their staff sufficiently to make up for the loss in hours of work and to maintain their output, and those which made no such increase in staff and consequently restricted output. In the first group the report estimates the increase in cost of production at 1.9 to 5.4 per cent, as compared with 1920; in the second the increase ranged from 3.7 to 11.8 per cent. While these figures give a general idea of the increase in expenditure due to the application of the act, as compared with other costs of production, they are of little use in determining its effect on the final economic strength of an undertaking.

"The report brings out the very different opinions which prevail in different circles on the advantages and disadvantages of the eight-hour day. Employers very largely support the view expressed by the Federation of Swedish Employers, that the 'introduction of the legal working day has been a great misfortune for the whole country,' while the workers have shown keen appreciation of the act and a determination to fight for its defense.

"In certain manufacturing industries the act has proved a powerful stimulus to reforms of organization and to a greater concentration of labor and an increase in its efficiency by technical alterations, and these gains have in some measure compensated for the reduction of hours of work. Industries that involve continuous processes have suffered most from the change, but the report recalls that the limitation of hours was particularly welcome to these shift-workers."

Posture in Women's Work

Serious Injury May Be Caused By Cramped, One-Sided Positions

THE effect on the physique and on the health of the industrial workers of the monotonous and rapid repetition hour after hour and month after month of movements in themselves light and simple has begun to challenge the attention of the medical profession. Especially is this true since so many such processes, characteristic of modern industry have been gradually monopolized, usually on a piece basis, by women whose deftness and swiftness have enabled them to take possession of occupations which did not require much muscular strength.

So far, although conclusive proof is lacking, the weight of opinion seems to be that serious injury may be caused by any work, the performance of which requires cramped, constrained, or awkward posture. Less general and less positive is the opinion as to the effect of the work on the nervous systems, especially in women.

Work that requires bent shoulders and drooping of the head compresses

the chest and interferes with the breathing, and this alone leads to many ills. It also forces the ribs and all that they inclose down upon the abdomen and tends to displace its organs. Among other results this pressure causes a "folding in" of the wall of the abdomen along the belt line and the partial stoppage of material moving through the intestines, and this leads to constipation, diarrhea, nervousness, abnormal fatigue, and headaches.

Work that requires a sideway "slouch" crowds the ribs between a low shoulder and a high hip on one side and expands them on the other side, interfering with the breathing and paving the way for tuberculosis. In girls and women this slouch also tends to displace other important organs.

Such results may be prevented or lessened by change of work; for instance, a change from work that requires stooping forward to work that requires reaching upward, or that requires a sidewise slouch, or that re-

quires no particular attitude. Such a change naturally involves a loss in speed, which for a time may cause serious money loss to a piece worker; but, especially in young girls, it will help to prevent ill health and possibly deformity.

Proper chairs are also helpful. For instance, as sitting all day at one's work is probably nearly as bad as standing all day, a combination of chair and desk (or work bench) whose relative heights would permit one to work with equal ease whether standing or sitting may be advantageous. Many types of "proper" chairs have been designed; but, naturally, few or none of them seem to be fitted to all types of work. Certain factors seem, however, to be advisable in all chairs.

All chairs, for instance, that are too high to permit the occupant's feet to rest firmly on the floor, should be provided with a foot rest that would prevent the lower part of the legs from dangling and the upper part (thighs) from pressing against the

Bent shoulders, drooping head, compressed chest, mark the position of this worker; all are conducive to bodily ills.

This posture does not impede the circulation and is in itself a mechanical safeguard against needless fatigue at the loom.

edge of the chair; practically, this means that women should not be called upon to use chairs built for men. Rests for the back are also extremely helpful in lessening fatigue.

That the constant repetition of a movement does in time affect the nervous system is more than probable, but how importantly it affects it has not been established. Anderson, for instance, states that girl after girl in a cigarette packing factory was found when off duty to be constantly repeating the motions she made while at work; and insists that such tendencies should be investigated.

The best preventives so far suggested seem to be the daily utilization of the forenoon and afternoon rest periods now in vogue in most factories either in complete rest or in exercising muscles not used in working time. When combined with periodic changes in occupation that call for changes in the muscles used such utilization should give effective help in preventing serious troubles.

Air Control in Bakeries

The problems of air control in bakeries are varied. The heat and humidity are such as to make cooling of the atmosphere necessary for the comfort and efficiency of the men. The accumulation of fumes along with the constant condensation of moisture produces odors that affect the product as well. Gases in the atmosphere have a much more serious action when temperatures are high and when the air movement is reduced.

Air control is simplified if in addition to forced ventilation provision is made for mechanically cooling and cleaning the air. These ends are served by passing the air through cooling chambers built in cells of five or six and arranged so the air can be shut from any one of them, thereby permitting the frost on the pipes to be melted and drained off, when it is again put into service. Such chambers are usually filled with 2 inch pipes and 3 inch centers and staggered so the air must strike the pipe surfaces on its passage up through.

Where bread is made on a large scale, some such provision as that described in the March issue of *Heating and Ventilating Magazine* serves the double purpose of safeguarding the workmen and reducing the temperature of the bread mixture. Mechanically operated dough mixers that work up from six hundred to twelve

hundred pounds of dough in one batch cause a rise of temperature in the dough from the heated arms that has a bad effect on the flavor of the bread and it is now considered good practice to keep the temperature of the mixture at or near 70 degrees F. Although the flour, yeast, etc., are mixed with water at a low temperature, ten minutes of continuous beating would raise the temperature above this point. To prevent this a supply of air cooled to a temperature of 40 to 45 degrees F. is fed into the mixer while operating. Quite often this air is washed.

The air should not be dry, consequently a large quantity of air at 50

Grease fumes are here collected by hoods over the vats. Workmen are thereby protected from the heat, and the finished product from deterioration from noxious odors.

degrees is better than a smaller quantity at a lower temperature, as the extra dryness of cold air would absorb moisture from the dough.

The air of the workroom in such a process is kept around 70 to 80 degrees by cooling the air for the workroom and circulating it through the room. Exhausts take care of special points where heat or fumes need to be reduced.

Important Nutritive Properties of Cheese

Estimates of the nutritional value of cheese have in the past been made on the basis of its high caloric content and its place in the dietary has been rather as an alternative for meaty foods than as indispensable for its intrinsic merit. All this is in a fair way to being changed on the basis of recent studies of food substances. S. K. Robinson, writing in *The American Food Journal*, as-

serts that without cheese the American dietary cannot readily be balanced in certain basic constituents.

The importance of cheese from the newer standpoint of vitamins, mineral salts, and certain amino acids is the basis of Mr. Robinson's study. In the process of cheese-making the greatest part of the casein and fat is brought down in the curdling process, leaving behind in the whey the milk, sugar, and albumin. Most of the mineral substances—the calcium, phosphates, and iron—are lost only to a small extent. The cheese is rich in fat soluble A, the growth vitamin, and Vitamins B and C are also retained to a smaller extent which has never been determined. Whatever is argued in favor of the nutritive value of milk can therefore be said of cheese which, for some uses, being the more concentrated food, enhances some of the benefits derived from a milk diet several fold.

Until recently the science of nutrition busied itself chiefly with the study of fats, proteins, and carbohydrates. The importance of mineral constituents is apparent, however, when it is considered that 2 per cent of the body weight is made up of calcium, and more than 1 per cent of phosphorus. Starling reports an interesting experiment which shows the importance of minerals in which rats fed upon a well balanced diet, but devoid of minerals, died sooner than another litter of rats placed upon a starvation diet.

Of the calcium found in the body, 99 per cent is found in the bone. Phosphorus, however, is distributed throughout the body. No other element has such a wide distribution, and the calcium and phosphate content of the mother's milk is very definitely related to the growth of the young animal. Rickets and soft bone in children, poor teeth, and similar troubles are directly traceable to insufficient calcium in the diet. Phosphorus is always found where growth is taking place. It is found in brain tissue, and nervous disorders have been ascribed to its deficiency. Lorand is quoted as saying the superiority of brain tissue lies chiefly in its phosphorus content and it is further claimed that fatigue of nerve and brain tissues should be met by diet. Robinson draws a parallel between the deficiency of the average American diet in calcium and phosphorus and the average American's nervous tension, and recommends an increase in the amount of cheese and milk to stabilize this inequality.

Social Service Ward

THE community at large often assumes and too often persists in a hopeless and certainly hapless mental attitude toward almost all aspects of the complex problems of social hygiene. The provision of bed facilities for venereal disease patients is a factor in the problem that has in the past received little attention. The social significance of these maladies is no longer questioned; the individual who has acquired a venereal disease involuntarily, or by accidental contact—which is very commonly nonsexual—is as deserving of community consideration as the individual who through deliberate sexual relations receives an acute infection that is a menace to his fellows. The former class of venereal disease victims even if in a late and noninfectious stage of the disease may face disablement and dependency, a condition that will as certainly, though less rapidly than acute disease, effect society.

An article in the April issue of *The Journal of Social Hygiene* on "A Social Service Ward for Women and Children: a Partial Solution of the Family Problems of Venereal Disease," is concerned with the problems mentioned above. The author of this paper, Dr. Victor C. Pedersen, states in the opening sentence that he has long "had the conviction that no hospital can do its duty by the community unless it has bed facilities for the so-called venereal disease patients." The bulk of the paper is concerned with the work of the Social Service Ward for Women and Children which was begun at St. Mark's Hospital, New York City, in July, 1922.

While in, and for, St. Mark's Hospital, this ward is temporarily independent of the hospital finance because the Social Service Committee and its friends meet the expenses, it is interesting to note that several private citizens, immediately on hearing of a few of the meritorious or pathetic cases, have liberally given financial support. During the first three months of operation with hardly any exception each bed has been filled all the time and a waiting list has existed.

Dr. Pedersen believes that ward service alone is fitting for the study of obscure and doubtful cases. "The first dictum (of the diagnosis of syphilis) is that if the patient has, or has had, the disease he himself and his physician must know the fact and the degree of the disease. In no other

way can the patient be induced to submit to, and the doctor plan for, the right methods and means of treatment. The second dictum is that if the patient has not and has not had syphilis he himself and his physician must know that fact. In no other circumstances will the patient be relieved from fear of the disease and the doctor from ordering unnecessary treatment."

During the ninety days covered by this report twenty-nine patients were received and fully diagnosed, and then returned for treatment to the agencies from which they came, or referred for treatment to the clinic of St. Mark's Hospital. Case No. 21, one of the many given in the report, illustrates the type and value of the work done in the ward. An illegitimate baby was born to F— E— after about a year's common law marriage with a young man who at first ran away but later returned with a willingness to marry the mother legally and religiously. During his absence she went to a hospital in Washington, D. C., where the opinion was given (seemingly by a nurse or through confusion of specimens or some other error) that she had true gonococcal infection. This news reached the young man who thereupon refused to marry her if this diagnosis was correct. After nine days in the ward F— E— was discharged without any suspicion of gonorrhea. The correct solution for this youthful misalliance had been found.

Such cases as these, and cases of hereditary or suspected hereditary syphilis, particularly in little children, make this a particularly appealing as well as valuable work.

Work of the Playground and Recreation Association

More than a hundred communities were visited during the past twelve months by field secretaries of the Playground and Recreation Association of America, who have helped in innumerable ways to set up recreational machinery and to oil that which is already existent. They have enabled cities to unify their work and thus effect economy, and have done much to interest the citizens in the work.

Another constructive part of the Association's field work is that of helping states and municipalities to pass bills permitting the establish-

ment of recreation systems. The past year has witnessed the passing of a significant amendment to New York State's recreation law empowering counties to establish boards of recreation and towns and villages to combine to conduct recreational programs. This bill will make possible more rapid development of public recreation in rural sections of the state. Des Moines, Iowa, was assisted in securing a law permitting a playground commission.

Besides the communities visited in person by field workers, there are thousands which are rendered service through correspondence. In all, fourteen thousand requests for information were received during 1922, requests not only from all parts of this country but from thirty-one foreign nations as well.

The publications of the Association represent a service which each year grows in importance. Through bulletins, handbooks, pamphlets and the *Playground Magazine*, practical suggestions and technical advice are made available.

The results of the work are to be seen on every hand. Playgrounds, swimming pools, public bathing beaches, community buildings, municipal camps and golf courses have in the past two years doubled in number. The report covers statistical summaries of activities in more than 2,400 towns in the United States and Canada, five hundred five of these being complete enough to compare and tabulate. Since complete data came in from less than 50 per cent of the cities studied, the report indicates only in a general way the tendency of the recreation movement in 1922. The 505 cities under paid leadership report on 4,601 recreation centers. Men workers employed number 4,204; women workers 6,663. The total number of year round workers is 2,026. Seventy cities report training classes for volunteer leaders.

Only fifteen cities reported on the value of playground sites presented to municipalities during 1922. In these the sum aggregated \$611,400. A total average of evening attendance at centers was 218,790 in 143 cities giving this record. The total expenditure reported in 472 cities was \$9,317,048.79. Bonds for recreational purposes were issued by eighteen cities amounting to \$1,155,180. The administration costs of the Playground and Recreation Association of America was \$183,975.58 during the same period. Every where better organization and official support are giving unity and direction to recreational effort.

Deficiency Diseases in the South

IT IS hard for dwellers in security, where hygiene and health are securely safeguarded, and where varied and abundant food is taken as a matter of course, to realize that the mountain people of our southern states, depending upon their own efforts both in sickness and health, undergo lives of hardship and privation and subsist on a dietary so restricted that deficiency diseases affect whole populations in given communities. Even where chickens are kept neither the fresh meat nor the eggs are used for food, but serve as a medium of exchange for salt, sugar, vinegar, molasses, soda, canned goods, such as salmon, peaches, and tomatoes, and cheap candy and tobacco. Very little fresh meat comes to the table, with the exception of pork at hog killing time. Facilities for cold storage being out of the reach of these isolated people, beef or lamb cannot be utilized and hence is not available for the table. Garden patches poorly cultivated and badly kept, give at best an insufficient supply of beans, turnips and turnip greens, potatoes, cabbages, beets, and onions.

Sara Merrill, commenting in *The Forecast* on the first nutritional survey of a rural community by the Children's Bureau, gives interesting

facts on the nutritional index of a mountain county in the rich and prosperous state of Kentucky. Among 149 children examined only 7 per cent were in excellent physical condition, only 18 per cent in good condition, only 35 per cent in fair condition, and 40 per cent were in poor physical condition. Undernourishment was the rule, and not the exception.

Inquiring next into the economic status of the families concerned in the study, housing, sanitation, water supply, and the available food supply were considered, and the food question was found to be the most important of all. In the final analysis the health of the children seemed to hinge on the amount of milk that was provided for them.

The cornbread and fat meat diet which was the common one when meat was omitted, is deficient in calcium, as well as protein and vitamin content. Though the diet was bettered by the addition of any one of the more common foods used in the community—beans, biscuits, sorghum, sweet potatoes—it still remained inadequate in some respects, most especially there lacked calcium and the fat soluble vitamin. Milk supplied all the deficiencies noted. Small wonder, then, says the report, that milk is

called a protective food. It is veritably the salvation of diets in this community.

Another study quoted by Miss Merrill was that reported by Fairfax Proudfit on some sections of the southern highlands revealed conditions even more deplorable. The increasing peril of pellagra throughout the South, together with the annual mortality from tuberculosis and other respiratory diseases, and the high rate of infant mortality, require that more attention be paid to the food deficiencies in the groups represented.

It is for this reason that the best work to be done in these outposts of civilization is accomplished through education. Ignorance, disease, and poverty, go hand in hand. Also, it is easy to understand that agricultural experts and teachers in domestic science are in such communities the advance guards of public health work. A trained woman, with a good cook book, and new farming methods can, according to Miss Merrill, at least in her own neighborhood, so manage her food resources as to change the condition from poverty to well being. Nowhere is there a more striking similarity between diseases and dietaries than in these isolated regions of the South.

Smallpox Control on Shipboard

ON FEBRUARY 14, 1921, the United States Battle Fleet with a personnel of approximately twenty-five thousand men arrived at Balboa, Canal Zone. On one of the battleships there were fourteen cases of mild smallpox and subsequently eleven additional cases occurred on the ship and three among the contacts at the quarantine station. The total number of cases in the outbreak was twenty-eight. There were no deaths. There were no secondary cases on the infected ship and no cases on any of the other ships of the fleet. The measures put in force for the control of the outbreak were so simple, cheap, and effective that they are considered worthy of record.

The infected vessel was placed in quarantine, but the restrictions thereby imposed were ameliorated in every way which was compatible with safety, e.g., the small boats of the

vessel were permitted to participate in the Fleet sailing and rowing contests and the men were allowed to go on fishing and swimming parties, the sole requirement being that they be accompanied by an officer who saw to it that no contact was had with the personnel from other vessels and that at all times the quarantine flag was flown by the small boats used by the men from the infected ship.

The entire personnel of the Fleet was immediately re-vaccinated and the company of the infected vessel was vaccinated and re-vaccinated until a successful "take" or a reaction of immunity was obtained on every man. All personnel was inspected by medical officers twice daily and any person remotely suspected of having smallpox or a temperature above normal was sent to the quarantine station. All actual patients were isolated in the wards of Ancon Hospital.

The vessel was not fumigated and no chemical disinfectants were used. All belongings of infected men, suspicious cases, and close contacts were sent ashore and sterilized with steam. All hammocks, bedding, and wearing apparel of the remainder of the personnel were thoroughly scrubbed with soap and water, dried in the sun and afterwards sunned daily. The interior of the ship was thoroughly scrubbed with soap and water and repainted. Scuttle-butts were flamed with a gasoline torch every hour. All mess gear was sterilized thrice daily by boiling five minutes after thorough cleansing in a boiling solution of soap and water. Men were required to wash their hands carefully in fresh water before each meal and were encouraged to bathe or swim at least once daily.

The vessel sailed in close quarantine, completing its fourteen day quarantine period at sea. Before sailing,

all sick were put ashore at the quarantine station in order that the vessel should have a free sick-bay should subsequent cases develop en voyage. Just prior to sailing, the temperature of all officers and men was taken and the entire ship's company subjected to careful inspection, all suspicious cases being sent to the quarantine station. No cases developed en voyage or subsequently.

Aside from the fact that the officers and men were deprived of shore liberty and could not visit other vessels or receive any person on board, the routine of the infected ship continued as though there was no epidemic. Supplies and mail were delivered at the gangway and moving picture exhibitions were given each evening. The vessel was not detained but allowed to continue without interruption its maneuvers with the Fleet. Except for the hospital charges and the cost of rations for men detained at the quarantine station, the vessel was put to no expense which it would not ordinarily have had. In any event, the paint would sooner or later have been needed and there was no destruction of property by fumigants of very dubious efficiency. Throughout the entire quarantine period, the ship's company was apparently contented and happy, certainly it was very good natured and patient. It is believed that the "sweet reasonableness" of the control measures may have contributed not a little to this end.

New Regulations for Training British Sanitarians

The new rules presented below which have been adopted by the General Medical Council of Great Britain for the diploma or degree in public health will be read with much interest by American health workers. The principles which have guarded the Council in designing these new rules are (1) that the scope of the study for the D.P.H. must be enlarged to include the new subjects that have become of vital importance in the public health campaign during recent years, (2) that the training should be made more practical than heretofore, especially in its administrative and sociological aspects, and (3) that the efficient medical officer of health must be a physician of maturity and clinical understanding.

Rule 1.—A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in medicine, surgery, and midwifery and his admission to the final examination for a diploma or degree in sanitary science,

public health, or state medicine.

Rule 2.—The curriculum for a degree or diploma in sanitary science, public health, or state medicine shall extend over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification.

Part I

Rule 3.—Every candidate shall produce evidence of having attended, during a period of not less than five months, at an institution approved by the licensing body granting the diploma or degree, practical instruction in:—

(a) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man (at least 180 hours, of which 150 must be in laboratory work).

(b) Chemistry and Physics in relation to Public Health (at least ninety hours, seventy in laboratory).

(c) Meteorology and Climatology in relation to Public Health (at least ten hours).

Part II

Rule 4.—Every candidate shall produce evidence of having received, during not less than eighty hours, at an institution or from teachers approved by the licensing body granting the diploma or degree, instruction in the following subjects:—

(a) The principles of public health and sanitation (thirty hours).

(b) Epidemiology and Vital Statistics (twenty hours).

(c) Sanitary Law and Administration (including public medical services) (twenty hours).

(d) Sanitary construction and planning (ten hours).

Rule 5.—Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized Hospital for Infectious Diseases, and has received therein instruction in the methods of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

Rule 6.—Every candidate shall produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a medical officer of health, who shall certify that the candidate has received, from this officer or other competent medical officer, during not less than three hours on each of sixty working days, practical instruction in these duties, and also those relating to:—

(a) Maternity and child welfare service;

(b) Health service for children of schoolage;

(c) Venereal diseases service;

(d) Tuberculosis service;

(e) Industrial hygiene.

(f) Inspection and control of food, including meat and milk.

Certificates of having received the prescribed instruction in Public Health Administration must be given by a medical officer of health who devotes his whole time to public health work; or by the medical officer of

health of a sanitary area having a population of not less than fifty thousand, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than fifty thousand.

Seamen's Rights to Medical Radio Service

The probability that some masters of sea-going vessels may not, as yet, have been fully informed in regard to the right of members of their crews to medical service by radio while at sea and to treatment in U. S. Public Health Service hospitals on reaching port has caused Surgeon General H. S. Cumming to direct the preparation and sending of posters giving full information to all vessels of the American Merchant Marine.

Curiously enough, this medical service is really a lot of subsidy to merchant ships and sailors. A century and a quarter ago, when Congress established the Public Health Service, under the title of the Marine Hospital Service, it directed it to render medical aid to every American seaman who applied for it; and that for this each seaman should pay twenty cents a month. This was in 1798; in 1870 the tax was doubled; but in 1888 it was abolished; and since then all such aid has been rendered free. Even the expense of calling the Service by radio from out at sea is borne by the radio companies without expense to ship or sailor.

The forthcoming poster announcement reads as follows:

The U. S. Public Health Service provides hospital care and outpatient treatment for sick and disabled seamen. Hospitals with modern equipment, skilled physicians, specialists, dentists, and trained nurses are open to all persons employed on documented American vessels, and to the coast guard, lighthouse keepers, and certain others who help to keep the flag on the seas. An ambulance will go to the dock at any time upon telephonic call from a ship's officer.

As you are proud of a good ship, take pride also in keeping your own body healthy. Most injuries are due to carelessness. Most diseases can be prevented. Prompt care of small injuries may save a limb. Early treatment for disease may save a life or prevent months of illness. Learn to keep well. Pamphlets on tuberculosis, venereal disease, and other common diseases are sent on request by the Surgeon-General, U. S. Public Health Service, Washington, D. C. A book, "The Ship's Medicine Chest and First Aid at Sea" will be sent on request to the master of the vessel.

Any Marine Hospital will prescribe emergency treatment through radio shore stations in conformance with the provisions herein outlined.

Routine Food Inspection an Effective Health Measure

In the year 1910 there were 378 deaths in Cincinnati in children under the age of two from intestinal diseases. Last year the total was eighty-six. While educational factors have been at work, much credit for this saving of infant lives belongs to the activities during the same period of the division of food inspection, according to the annual report made in the May issue of the *Cincinnati Sanitary Bulletin*.

The Cincinnati supply of approximately thirty thousand gallons of milk daily comes from three states—southern Ohio, northern Kentucky, and southern Indiana. Marked improvement in the way of new barns, separate milk houses, milk coolers, sanitary equipment and better methods of milking were noted on the farms by field men who made 7,500 inspections. Five hundred and fifty producers who were unable to meet our requirements, decided or were requested to discontinue business. Fifty-six hundred notices were sent out to the producers, most of them letters of instruction. In addition to these, 17,000 educational pamphlets were distributed covering clean production and transportation. Permits at the rate of fifty cents for each six months were issued to milk shippers who comply with regulations. The milk is distributed by forty-five milk plants operated under a permit system.

Tremendous strides have been made during the past year in the retail industry. Three new milk plants were built, five completely remodeled, ten were equipped with mechanical refrigeration, twenty-two bottle and ten can powerwashers and sterilizers were installed.

While it is important and essential to supervise the product at the source of production, the real test of purity comes through chemical, bacteriological and sediment tests of the milk itself. The introduction of the sediment test has been a great stimulus for clean milk. One pint of each shipper's product is filtered through a cotton disk which is mailed back to the producer with such comments as may

fit the case. Thirty-one thousand six hundred and eighty-one samples were taken from milk plants, receiving stations in the country, retail wagons, restaurants, hospitals, and public schools; and of this number 8,788 were for the sediment test, 9,475 for bacteria, and 13,418 for chemical analysis.

At present all milk sold in Cincinnati, with the exception of certified and inspected, is pasteurized. Through pasteurization, the dealers have eliminated waste and are no longer harmed by milk-borne epidemics and subsequent loss of trade. In the old days, drinking milk was like a lottery from which one might draw an attack of typhoid fever, diphtheria, scarlet fever, septic sore throat, or bovine tuberculosis. No milk-borne epidemics have been noted since 1915, when universal pasteurization became effective.

During the year lay inspectors visited as often as time would permit, all establishments where foods are stored, packed, processed or sold. These include all restaurants, groceries, bakeries, meat stores, candy, ice cream and beverage manufacturing plants, and all incoming carload lots of fruit and vegetables. Meat shops and ice cream plants operate under a permit system at the rate of one dollar per annum. As the food inspector makes his rounds, samples are collected and subjected to chemical and bacteriological examinations for evidences of decomposition or adulterations, some of which menace health and life, while others are purely commercial frauds. Interstate violations are promptly referred to the Federal authorities.

During the past year 42,182 animals of the beef, sheep, goat, and swine kind were slaughtered under municipal inspection. This constitutes ap-

proximately 8 per cent of the total. Inspection is limited to those doing an interstate business. The interstate shipment of meat without Federal inspection is prohibited. Municipal inspection is carried out as prescribed by the United States Bureau of Animal Industry. Diseased animals are

disposed of according to the extent and character of the infection. Animals are either passed for food and so branded, or condemned outright; or passed with restrictions—as swine for lard, beef for sterilization. Condemned animals or parts are placed in steel tanks and cooked for not less than four hours under high pressure. The inedible grease so

obtained is used for soap, glycerin and other byproducts, and the residue is dried and used for land fertilizer.

Graduate veterinarians with years of training in animal pathology, abattoir sanitation and meat-processing are with us in the service. All animals offered for slaughter are inspected anti- and post-mortem. Inspection of meats in butcher shops, for evidence of decomposition, is the task of lay inspectors. A careful scrutiny is always made for the brand of Federal or municipal inspection. The skilled veterinarian alone is qualified for abattoir work.

Last year 440 animals were condemned outright and 10,629 primal parts. Sixty-nine swine were passed for lard; 585,400 pounds of sausage and lard were processed under inspection; and 116,000 pounds of various meats and sausage were condemned as unfit for food. The importance and necessity of this work must be perfectly obvious when we consider the animal diseases transmissible to man, notably bovine tuberculosis, the parasitic diseases, and meat poisoning.

The condemnations for 1922 totaled \$173,000.00. There were 24 prosecutions in the municipal court for violation of the pure food laws.

Dr. C. C. Pierce, senior surgeon of the United States Public Health Service, has arrived at Tampico, Mexico, to make a two-month's survey of the yellow fever situation at ports on the east coast of Mexico.

LATE HEALTH DECISIONS IN THE COURTS

BY DOROTHY KETCHAM, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

CANCER which developed after an injury was the basis of compensation by the Supreme Court of Colorado, January 8, 1923. While employed by the coal company, John Seitz, the employee, was struck in the face by a piece of coal. Later, carcinoma, a form of cancer, developed there, from which he died.

It was said first that there was no finding of fact that the accident was the proximate cause of the cancer or that the decedent suffered any disability as a result of the accident. This was not sustained by the Commission's findings. "That while the decedent was engaged in loading coal he was struck on the cheek by a flying lump of coal . . . beginning with the time the decedent's face became sore and swollen, his condition became steadily worse and finally culminated in his death on August 26, 1921. No intervening cause is shown that would, or does, account for the sudden change in decedent's condition." The physician's statement in part was "It is a well established fact that irritations and traumatism undoubtedly start cancer in some cases. . . . Men are struck in the face with pieces of coal in mines thousands of times and nothing happens, but at the same time a trouble might follow such an injury in another instance." The court concluded that there was "substantial and credible evidence to support the findings, and consequently the Commission in basing them upon such evidence acted within its powers."—*Canon Reliance Coal Company v. Industrial Commission*, 211 Pac. 867.

INJURY to an eye which in turn caused hemorrhage came before the Supreme Court of Oklahoma recently. An employee of the Winona Oil Company went to the company supply store for tools. After getting them he started out of the store to his car and stepped off a platform about two and one-half feet high. The tools being in his arms he received a severe jar, which caused a rupture of a blood vessel and a hemorrhage in the vitreous humor of the left eye. The evidence of the attending physician tend-

ed to show that for all practical purposes he had lost the use of the eye and the Commission award compensation for the permanent partial disability for the loss of an eye.

The petitioners claim that, first, this was not an accidental injury within the Workmen's Compensation Act and, secondly, that no disability resulted.

The Court pointed out that Workmen's Compensation Laws are to be construed fairly, even liberally, in favor of the employee. It is agreed that the stepping off the porch was not an accident but the untoward event was the severe jar rupturing the blood vessel in the eye. An accident has been defined as "an unlooked-for mishap, or an untoward event which is not expected or designed." "Unquestionably the violent jar which ruptured the blood vessel in the respondent's eye was an unlooked-for and untoward event. It is obvious that if in such an event a result had been expected, the respondent would not have stepped off the porch, or would have unloaded the tools and gas fittings which he was carrying before he stepped from the porch in order to prevent the rupturing of blood vessel in his eye." The injury was held to be accidental.

"The primary purpose of all workmen's compensation for injured employees for injuries accidentally received in the course of their employment. The compensation provided for in such laws is intended to operate and fill the place of an accident insurance policy. The great army of employees are indispensable in carrying on the great industrial operation of the nation in the production of the necessities of life. In order to dispense with a great volume of expensive litigation, workmen's compensation laws have been substituted for the ordinary common law action for damages for injured employees. The chief purpose of all workmen's compensation laws being to compensate injured employees speedily and in an inexpensive manner. Then the necessary cost of such compensation is to be charged as a part of the cost of production. Therefore, technical rules

and fine-spun theories have no place in the construction of such laws. The award of the Industrial Commission is affirmed."—*Winona Oil Company v. Smithson*, 209 Pac. 398.

ON JULY 31, 1918, a carpenter was injured on his right forearm by a rusty nail. The injury became serious, resulting in an endocarditis which caused his death. The question of the sufficiency of evidence was raised by the Supreme Court of Pennsylvania, October 20, 1922. The court states: "An examination of the testimony, and especially that of the doctors, shows that deceased, previous to the blood infection, was a strong healthy man, working regularly at his trade, and at no time before the accident had experienced symptoms of embarrassed heart action. The physicians who examined or treated him testified that the endocarditis from which he suffered was the result of the injury referred to. Without referring to the medical testimony in detail, we find it ample to sustain the finding."—*Guthrie v. Thompson Starret Company*, 118 A. 735.

AN EMPLOYEE who suffers an injury to his eye which causes permanent impairment of the vision is entitled to compensation, although the vision can be rendered normal by the use of glasses according to the New Jersey Court of Errors and Appeals, June 23, 1922.

As the statute declares the decision of the Court of Common Pleas upon questions of fact to be conclusive and binding, the finding of that court of a one-third loss of vision to the left eye is accepted as a finality. The question is raised "whether there can be said to be a permanent injury where after an accident to the eye the normal sight therefrom can be obtained through proper lenses in glasses, for it is admitted that the petitioner's sight with glasses is normal. The contention of the prosecutor must rest upon the proposition that a workman with glasses is the equal of a workman who does not have to depend upon glasses for proper vision. . . . It seems to us, that, where one must depend upon some mechanism, braces or glasses, to enable a member of the body to function properly, and such necessity is the result of accident, that such member is permanently impaired. An eye dependent upon glasses for normal vision is not as good as an eye which requires no such aid for its vision."—*Johannsen v. Union Iron Works*, 117 A. 638.

SANITARY AND HYGIENIC ADVANCE

Improvements in Activated Sludge Treatment

C. L. Peck (*Engineering News-Record*, March 22, 1923, 90, p. 12522) believes that the total cost of sewage treatment by the activated sludge process including sludge disposal can be brought down to between twenty and thirty dollars per million gallons. He advocates preliminary treatment by sedimentation and screening, preliminary aeration for the oxidation of readily oxidizable substances, and aeration in the presence of activated sludge, aided where possible by certain substances like iron, salts, nitrates and gas wastes which act like catalysts, with subsequent sedimentation. The author thinks very favorably of paddle aeration as worked out at Sheffield and elsewhere as compared with bubble aeration and is a strong believer in the dewatering of sludge from preliminary sedimentation and from the activated sludge treatment, by his own process of flotation, by the MacLachlan process or by vacuum filtering on the Oliver plan.

Mortality in Alexandria, Egypt

The conception that tropical climates are necessarily unwholesome is not true so far as the city of Alexandria is concerned according to Dr. Emil Gotschlich (*Ztschr. F. Hyg. u. Infektionskrankh.*, Vol. 93, p. 546, 1922). His statistics indicate that the death rate of adults both native Egyptians and European whites is equal, and by no means excessive. The natives show an enormous infant mortality but the Europeans do not and although the infant mortality rises in the warm season this is not the case with adult mortality even among the foreign born.

Public Bathing Beach Chlorination

Baker describes chlorin treatment of the water at a public bathing beach which is thought to take care of any ordinary contamination of the water by infected bathers as well as the destruction of bacteria from constant sewage pollution. (*J. A. M. A.*, March 31, 1923, 80, 13, p. 907).

The treatment is effected by means

of a chlorin apparatus mounted in a motor boat. The chloroboat cruises back and forth outside the life lines at the beach. One man cares for the boat and its engine while another runs the chlorin apparatus and the water pumping engine. The latter makes frequent rough colorimetric tests of the amount of free chlorin in the water and by varying the speed of chlorin introduction and the proximity of the boat to the beach tries to keep the residual chlorin content of the beach water between 0.02 and 0.5 parts per million. If the free chlorin is kept below 0.5 parts per million its presence is not detectable by the average bather and life guards who have been in the water more or less every day for two years have shown no irritation of the skin or mucous membranes.

Treated water on this bathing beach (Washington D. C. Tida Basin) is found to average less than 100 bacteria per c.c. and *B. coli* is occasionally found in two or three of five 10 c.c. portions, whereas the untreated entering water (from the Potomac River) has a total count of 175,000, and 500 *B. coli* per c.c.

New Sewage Treatment System

A new system of sewage treatment, named "sept-aer-sed" has been in operation at Graham, Tex., since June, 1922. As the name implies it consists of septic tanks, aeration chambers, and sedimentation chambers.

In the ordinary activated-sludge process it is estimated that 95 per cent of the air is used exclusively for mechanical agitation. In this new system the preliminary treatment in a septic tank reduces the suspended solid content of the raw sewage to such a point that only the very finely divided matter passes into the aeration chamber where, with a greatly reduced volume of air, aeration is carried to a stage that results in the elimination of excess activated sludge.

Elrod reports (*Eng. News-Record*, April 5, 1923, 90, 14, p. 620.) the chief advantages of this system as: (1) The complete elimination of the troublesome excess activated sludge. (2) The small volume of air required for the production of a stable final effluent.

(3) The lack of necessity for technically skilled operatives.

The recovery of *B. anthracis* from a shaving brush five years after it caused a malignant pustule is reported by Kingsbury (*Brit. M. J.*, March 10, 1923, 3245, p. 417).

Causes of Industrial Eye Injuries

Figures from the National Bureau of Casualty and Surety Underwriters, covering about 10 per cent of the total eye injuries of the country, show a total of 32,825 injuries requiring medical aid, 7,826 tabulative injuries, and 1,400 compensable injuries. These three categories are not mutually exclusive. The total cost of all the injuries amounted to \$671,569, of which the medical cost was \$186,602 and the compensation cost \$484,967. The average compensation cost per compensable case was \$346 and the average total cost per case requiring medical treatment was twenty dollars. (*Monthly Lab. Rev.*, March, 1923, xvi, 3, p. 110.)

Flying particles and objects account for 70 per cent of the total injuries and 50 per cent of the cost. Of these abrasive wheels produce 31 per cent of the medical-aid injuries but only about 9 per cent of the total cost; objects flying from tools handled by workmen cause 9 per cent of the accidents, representing 15 per cent of the cost; and flying particles not otherwise classified cause 30 per cent of the accidents and 24 per cent of the cost.

All of the foregoing indicates the importance of goggles and other eye-protecting devices in reducing the hazard resulting in eye injuries.

The Problem of Preventive Medicine

This problem is discussed by S. R. Haythorn, (*Journal A. M. A.*, March 31, 1923), under two general headings: (1) influences that are developing an ever increasing demand for disease prevention in the practice of medicine, and (2) preventive medicine in the medical curriculum. Haythorn urges that the teaching courses in all departments be reviewed thoroughly, with the object of stressing successful preventive methods for the benefit of the students. The teaching should be carried out with a view to informing the student of the best preventive measures available, and should be directed toward preparing him for leadership in progressive health movements.

Etiology of Miners' Nystagmus

Robson (*Brit. M. J.*, March 31, 1923, 3248, p. 570) has studied the volatile contents of coal in various regions in relation to the incidence of miners' nystagmus.

Coal Field	Volatile Contents of Coal	Incidence of Nystagmus
Nonmouthshire	29.50%	4.56%
Glamorganshire, East..	29.50%	2.22%
Glamorganshire, West..	25.50%	1.90%
Cardiff	11.86%	1.15%

Inference that a gas (or gasses) is the generic cause is supported by observations that have been made in the Rhondda Valley. From 1909 to 1920 there were two peaks of high incidence of nystagmus (1914 and 1920) and during this period there was a steady increase in the use of lamps. All this is averse to the theory that lighting is the cause of this affliction of the miners.

Robson also states that it takes about twenty years for nystagmus to develop in hard coal workers while soft coal workers may be afflicted in two years, a fact tending to support the theory that the nature of the coal is of some importance.

Danger of Arsenic in Clothing

Recently an active advertising campaign has been utilized to promote the use of a solution containing arsenic (equivalent to 0.05 per cent arsenic pentoxid) as a larvicidal spray for clothing. It is proposed to induce manufacturers of woolen garments to have their materials treated with the arsenic solution to protect the cloth against moth invasion; in turn, the retailer guarantees to the consumer that the fabric will remain moth free. In view of past experiences with arsenic poisoning and the almost universal legislation against its presence (except in minute traces) in foodstuffs, wall paper and even in dyed clothing, this propaganda is surprising. Unfortunately, the public is led to believe that the government endorses the product. The advertisements state that "*Larvec*"—as it is now called—was subjected by the U. S. Bureau of Entomology to the severest test possible and approved. An inquiry reveals that the bureau does not endorse *Larvec*, nor were the tests the severest possible. It seems that a naval commandant requested the product to be examined and then turned the report—favorable as far as it went—over to the manufacturers, who capitalized it. Before it is too late, it is hoped that dealers in wool clothing will not allow themselves to be parties to the distribution of this potent poison, nor allow their names to be used in connection with a mislead-

ing endorsement. (*Jour. A. M. A.*, April 14, 1923).

Research Work of the A. S. of H. and V. Engineers

The American Society of Heating and Ventilating Engineers has evidenced remarkable vision and courage in the establishment of a special research laboratory conducted in cooperation with the United States Bureau of Mines at Pittsburgh, Pennsylvania. The *Journal of the American Society of Heating and Ventilating Engineers* for March, 1923, contains some of the first communications from this experiment station. The most important paper (by McConnell and Houghten) is a study of physiological reactions to high temperatures and humidities which includes the most careful study yet made of the limiting temperatures and humidities which can be endured when at rest in still air. A wet bulb temperature of 90° is the upper limit of compensation and a rise in the pulse rate appears to be the most sensitive index of discomfort.

Houghten and Yagloglou report a chart based on laboratory studies indicating the combinations of temperature and humidity which are found to be equally conducive to comfort in still air. According to these investigators the effective temperature coincides with the wet bulb temperature at about 132°, but at 32° the effective temperature coincides with the dry bulb temperature and the effective temperature lies somewhere between the two.

Margaret Ingels describes a new apparatus for determining atmospheric dust based on the increased resistance in a filter. This apparatus devised by Anderson and Armsbach is recommended on account of the fact that it can be used in the field without any technical knowledge on the part of the analyst but it obviously can not be expected to yield results in any way comparable to those obtained from procedures which involve direct counting or weighing of dust particles.

Absorption of Calcium in Tuberculosis

Studies by Maver and Wells "have failed to produce any experimental evidence which supports the empirical clinical evidence that calcium administration has a favorable influence upon the course of tuberculous infection. They do support the evidence of chemical studies that administration of calcium salts by mouth does not appreci-

ably increase the amount of calcium in the blood and tissues, for this is normally maintained at a level not far below the saturation point of the body fluids." (*Am. Rev. Tb.*, March, 1923, vii, 1, p. 1.)

Accidents in Mines

Rice and Adams review (*Am. Lab. Leg. Rev.*, March, 1923, xiii, 1, p. 31) the coal mine accidents for 1922. While there was a slight reduction in the total number of accidents for the year 1922, the accident rate in relation to the quantity of coal produced was higher than for 1921.

The past year witnessed fourteen major disasters (those causing five or more deaths) with a loss of 280 lives. All but three of these disasters were mine explosions. During 1921 but five major disasters were recorded with a loss of thirty-four lives.

The fatalities from gas and dust explosions per million tons mined was 0.229 in 1921; in 1922 this rate was 0.675 or nearly three times the rate for the previous year. Less than ten per cent of all mine fatalities, however, are caused by explosions while nearly 50 per cent result from falls of rocks and coal. During the past year falls of rock and coal have resulted in the deaths of 900 men, or a death rate of 1.955 per million tons mined. An examination of mining records over a long period of years discloses little if any improvement in this class of mine accidents. The probable cause of this condition is stated to be the miner's desire for production rather than safety.

Comparisons are also made with the low rate shown in the experience of the British coal fields.

The Effect of Diet on Intestinal Protozoa

Hegner reports that changes in diet exert a radical effect on the distribution of intestinal protozoa in tadpoles (*Journal of Parasitology*, ix, 51) and in rats (*American Journal of Hygiene*, 111, 180). In the case of the rats the replacement of a vegetable by an animal diet led to a marked decrease in the number of protozoa present, particularly in the case of *Trichomonas*.

Correction

The map of "State and Semi-State Institutions of Pennsylvania" published on page 364 of the June issue of *THE NATION'S HEALTH* by the Public Charities Association of Pennsylvania. It was incorrectly credited to the State Department of Public Welfare.

NEWS FROM THE FIELD

Tuberculosis in Paris

Tuberculosis still causes one-fifth of all the deaths in Paris, according to the "Bulletin de Statistique Municipale" just received.

During 1922, in Paris, among the 40,583 total deaths occurring in that city, 8,077 or 20 per cent were caused by tuberculosis. The post-war census of 1921 showed the population of Paris to be 2,906,472.

The mortality from tuberculosis of all forms in Paris in 1922 was at the rate of 297 per 100,000 inhabitants. The deaths from pulmonary tuberculosis in 1922 numbered 6,884, as against 7,078 in 1921, 6,599 in 1920 and 6,966 in 1919—namely, during the war years of 1914 to 1918—the number of deaths from pulmonary tuberculosis in Paris ranged between 8,337 and 9,218.

Connecticut Program for Backward Children

Connecticut is providing for her 3,500 backward and subnormal children, and more than 40 classes are reported as already formed in Bridgeport, Hartford, Manchester, New Haven, Somersville, Stamford, Torrington, and Waterbury. More than six hundred children have been placed in these classes, an average of fifteen children to each class. The majority of these children are undoubtedly subnormal to some extent, belonging to the definitely feeble-minded, the border line, and the dull normal groups. Some schools have two types of classes—one for children who are definitely feeble-minded and one for those who are merely backward.

Extensive Health Service for Northwestern Policyholders

The Northwestern National Life Association has conducted a health service for all policy holders and their families for seventeen years and now proposes to extend free general advice on any medical, hygienic, or sanitary subject of interest to policy holders; free periodic physical examination; governing principles on "how to live to be 90," and clinical thermometers at cost, with advice on home or office ventilation. Additions service to large policy holders may be had on request.

Pennsylvania Has Recreational Bureau

Pennsylvania has a state bureau to assist in recreational development. It assists in the selection and coordinated development of buildings and sites for playgrounds and other public uses, and undertakes to gather and disseminate general information upon the accomplishments and accepted procedure in other communities. The Bureau has been able to demonstrate by example the value of good design and has been instrumental in setting up a visible standard which has aroused public interest to an appreciation of the needs and possibilities of a broad recreational program.

In addition to the formulation and adoption of Standards for Out-Patient Service in Pediatrics, the section on pediatrics of the Associated Out-Patient Clinics has selected one institution in which to demonstrate well rounded service in pediatrics. After a careful study of various clinics of New York, the Children's Medical Division of Bellevue Hospital was chosen.

At Bellevue a demonstration of complete unity between the in-patient and out-patient service will be made possible by improvement of record transfer between ward and out-patient department. Through the employment of a part time admitting physician, improved methods of admission and distribution of patients (especially the control of contagious disease) will also be worked out. An appropriation from the Committee on Dispensary Development of the United Hospital Fund has been made to meet extra expenses involved in the clinic for this year.

The demonstration at Bellevue began February 1, and its results will be closely followed by the Section during the year.

The Executive Committee are also working on a plan for the study of results in pediatric out-patient service, and are at present trying out a tentative plan of study in three representative clinics. Their aim is self-analysis: to determine to what extent the clinic work is not effective; why, and how its effectiveness can best be tested at periodic intervals.

Further reports of the demonstration at Bellevue, and the plan for

studying results will be published from time to time so that the work may be of value to those interested in pediatric out-patient service.

Major Boyd-Hamilton Figures on Illegitimacy

The following figures on illegitimacy in different countries were presented in the House of Commons, London, by Major Boyd-Carpenter, parliamentary secretary, Ministry of Labor:

Countries	Year	Number	Rate per 10,000	
			Total Live Births	
England and Wales	1921	38,618	455	
Scotland	1921	8,756	711	
France	1913	65,568	879	
Italy	1917	32,833	477	
Belgium	1913	10,975	641	
Holland	1920	4,112	213	
Norway	1917	4,466	699	
Sweden	1919	15,060	1,494	

New Health Legislation on Statute Books

According to data of the National Health Council over two hundred new health laws have been added to the statute books, so far this year. Sixty-eight of these were in New York; Iowa has 24 new health laws; Minnesota, 21; Ohio, 13; Connecticut, 11; and Idaho, 10. The remaining states each passed less than 10, as in New Jersey, where 44 measures were considered and only four passed. Of course, in many of the states, legislation which would have been detrimental to health, as chiropractor, anti-vaccination and similar bills, were defeated.

Thirty-nine states have now accepted through legislative enactment the federal maternity and infancy act, and legislation is pending in three other states. Some of these thirty-nine were passed last year, however.

Of the new health laws of this year, forty concern municipal health, though the bulk of these are in New York state. Tuberculosis comes next with twenty-three new laws, and foods and drugs are third in the list with 19. There were eleven new laws on state health, not including appropriation measures, and 8 new narcotic acts. Physical education laws were passed in a number of states. The chiropractors got new legislation in only two states, and one of these laws was an amendment of existing statute. This cult now has recognition in over twenty-five states, however. Crank legislation, such as the ubiquitous anti-vivisection and anti-vaccination bills were, as usual, defeated. A comprehensive general health bill was vetoed in Wyoming and medical practice act concerning use of degrees was vetoed in California.

Unemployment Insurance Involves Mental Tests

Psychological ratings for all employees would be a necessity under the system of unemployment insurance predicted as a logical extension of present insurance business by J. D. Craig of the Metropolitan Life Insurance Company. The beneficiaries would be employees thrown out of employment by conditions beyond their control. Such protection could be administered by insurance companies just as workmen's compensation and group insurance are now carried. A working period prior to compensation for unemployment would need to be established, and the "drones, wanderers, and restless would be left to their own devices." It is in the detection of the "rovers," a distinct psychologic entity, that modern methods of psychology would be requisite.

Peru Educates on Community Hygiene

A group of public spirited inhabitants of Chorrillos, Peru, has organized a public extension university course with special emphasis on labor problems and personal and community hygiene. The course is under the patronage of the municipal council, which is cooperating in every possible way with the educators.

"Work, discipline, and good will will wipe out the offense committed and lead man again into social communion." This is the legend above the new white marble administration building of the Sao Paulo State Penitentiary, Brazil. A wise administration has built up a remarkable reformatory institution at this point, to which a very small proportion of inmates return for a second term. In rather sharp contrast with this inscription and the method which it indicates is the inscription over the portal of what is counted a model prison in one of our northern states, which reads: "He who enters here leaves hope behind."

Indiana Surveys All Outing Places

The Water and Sewage Division of the Indiana Department of Health is equipping a truck with laboratory facilities to conduct a sanitary survey of all lake resorts, outing places, and tourists' camps in the state of Indiana. The traveling laboratory will be established at strategic points in the lake region of northern Indiana from which points a field survey will be extended. The object is to elimi-

nate "typhoid traps" and to create "safe beauty spots" for the whole people.

Oregon Enumerates Crippled Children

Oregon has passed an act providing for the enumeration, instruction, and cost of instruction of crippled children within the state whose physical conditions makes it impossible for them to attend the public schools. A penalty for the violation of the law is provided and previous laws in conflict with it are repealed.

England Develops Occupation for Defectives

Occupational centers for mentally defective children in England, though constituting the most recent development in the training of defectives, now number sixteen and the number is still increasing. In some centers the work is further extended by the organization of special classes for defectives over school age, who are unemployed or unemployable. Home training for such children is painfully inadequate, and at these centers opportunities are afforded for learning muscular control, cleanliness, obedience, and simple manual work under skilled supervision through the Central Association for Mental Welfare.

Seven Per Cent of World Population in Cities

A total population of 1,804,187,631 peoples of the globe, only 7 per cent of which is in cities of more than 100,000 inhabitants, according to statistics compiled in Berlin on the basis of 1922 census reports. Only thirty of the seventy nations listed have cities of 100,000 or above.

Nevada Has Hospital Enabling Act

Nevada now has a public hospital enabling act whereby 25 per cent of the tax payers in any county that wants a public hospital can present a petition to the commissioners, who will put the question on the ballot at the next general election and, if carried, the commissioners are empowered immediately to proceed to provide a hospital. A nurses' registration law was also passed under which graduate nurses and all other nurses who have had twenty-eight months' training in a Nevada hospital, under the direction of a physician licensed in that state, are entitled to register without examination, provided this formality is complied with prior to July 1.

Chile Undertakes Model Housing Schemes

A practical example of Chilean interest in model housing is a group of seven cottages built by State Railways in Valparaiso for some of their employees. Planned to form an attractive architectural whole and set in their own gardens, the cottages have three or four rooms in addition to kitchen and bath, and are equipped with electric lighting. A bill is pending in the Chilean Congress for a model housing project to be carried out at the government naval station at Talcahuano. It will include 238 houses, schools, a theater, drinking water supply, and a sewer system.

Rickets Widespread in Germany

The Berlin correspondent of the *Journal of the American Medical Association* reports that, as a result of food scarcity during the war, rickets is highly prevalent among German children and permanently crippling conditions are widespread.

Professor Engel in Dortmund gave recently some useful statistics on the incidence of the disease. Of 1,384 children in Dortmund belonging to the 2-10 age group, 594, or 42.8 per cent, were suffering from rickets. The percentage of severe types of rickets was very large, approximately 21.3 per cent of those affected, while 40 per cent were of the moderate type. On an average, 10 per cent of all children demonstrated presented severe or extremely severe types of the disease. That is an extraordinarily high percentage, which is of serious moment in view of the sequels of the severe types. In an inquiry into the causes of rickets, Professor Engel's table, which appears to establish a connection between unfavorable housing conditions and rickets, may be of value.

Kentucky Code Commission Reports

The Kentucky Children's Code Commission report covering child welfare legislation prior to and through the legislation session of 1922 in collaboration with the National Child Labor is available on application to the Commission at 428 South First Street, Louisville, Ky.

Washington Representative of Health Council

Miss Cornelia Lyne, of the American Child Health Association, will serve temporarily as the Washington representative of the National Health Council. Her address is 532 Seventeenth St., N. W., Washington, D. C.

Rockefeller Aid to English Public Health

As a result of the Rockefeller Foundation gift of nearly six million dollars, the largest sum ever given in England for educational purposes, the corner stone was laid on May 31 of the new hospital buildings of the University College Hospital, London, and the new medical research building declared open.

Professor G. Elliott Smith, dean of the University College Faculty of Medical Sciences, discussing with The New York Times correspondent the Rockefeller Foundation's gift said:

"It has enabled the University College to erect a new department of anatomy and the University College Hospital to extend and develop the opportunities for teaching and research in medicine and surgery. Thus it has enabled these institutions to realize what for a long time has been their aim, namely, to effect a much more intimate cooperation among the different departments concerned in medical education and a fuller development of the opportunities for research, with precision of aim and the widest possible outlook.

"The new building has made it possible to restore the teaching of microscopic anatomy to the Department of Anatomy and to make provision for the full use of x-rays for teaching and research in anatomy. In addition there is provision for investigations in experimental embryology, and the factors that influence growth and for the use of ultra rapid cinematography as a means of analyzing and studying animal movements.

"Within the new institute it has also been possible to create special departments for physiological chemistry, for anthropological studies and for the history of medicine.

"Even more important than the provision of accommodation and equipment for study and research is the bringing together in one building, with a library and staff rooms in common, of all the workers in the different departments of medical study, who will also be put in the closest possible collaboration with those working in the hospital. Above all, the gift of the Rockefeller Foundation has made the University College and the hospital associated with it a permanent symbol of the friendship and community of aims of the medical men on the two sides of the Atlantic and an instrument for maintaining and developing this cooperation and extending its influence throughout the British Empire and elsewhere."

New Athletic Officer at Annapolis

The position of athletic officer, regarded as one of the most important on the staff at the Naval Academy at Annapolis will shortly be filled by by Commander Byron McCandless, now in Turkish waters.

Commander D. L. Howard was relieved of this duty about the first of the year, and Lieutenant B. F. Perry has been acting in that capacity since.

High Schools Now Adopt Hygiene Courses

The Board of Estimate of New York City, after exhaustive tests as to the merits of the Red Cross course in home hygiene and care of the sick, on May 18 appropriated funds to install it as part of the curriculum in nine girls' high schools. Plans are under way for its extension to other high schools as soon as the teaching facilities permit. The seven Red Cross nurses available for the purpose are for the first time in the city's history enrolled as regular high school teachers.

The Red Cross Promotes Indian Welfare

A plan is under way by the Red Cross to solve the health problems of the Indian through aid in medical and social lines. It is proposed to begin with community centers at Zuñi, on the Zuñi Reservation; Dulcem Jicarilla Reservation; Oraibi, Arizona; Tohatchi, N. M., Pima Reservation; and in at least two pueblos of the Rio Grande Valley. Where community centers are impossible, the Red Cross will aid the local hospitals and schools in some way. A field worker will be appointed to the work and another year the Junior Red Cross will be assigned to certain parts of the project.

Miss Abbott Elected Head of Social Workers

Miss Grace Abbott, chief of the children's bureau of the Department of Labor, was unanimously elected president of the National Conference of Social Work at the business session of the fiftieth anniversary meeting. Toronto, Ont., was selected as the scene of the next convention.

Californians Using Much More Milk

An increase in the consumption of dairy products in the state of California is reported for the past year amounting to 13,500,000 gallons; also a per capita increase in the consumption of butter from 21 to 22½ pounds.

Social Welfare Publishers Hold First Meeting

The first annual meeting of editors and publishers of social welfare publications in the United States and Canada was held at Washington, D. C., on May 18. The meeting was held in conjunction with the fiftieth anniversary of the National Conference of Social Work.

A committee was appointed to arrange for subsequent meetings and to work out ways and means for co-operation in editorial, circulation, and advertising problems.

Among the speakers at the meeting were: Paul Kellogg, *The Survey*, George J. Hecht, *Better Times*, Harold S. Buttenheim, *The American City* and Phillip E. Jacobs, *Journal of Outdoor Life*, all of New York.

Rockefeller Foundation Grants Many Fellowships

During 1922 a total of 226 fellowships were granted by the Rockefeller Foundation and its various boards. Seventeen countries were represented in these fellowships. Seventy-nine were administered by the International Health Board, sixty-two under the China Medical Board, and sixty-two were fellowships in physics, chemistry, or medicine, supervised by a committee of the National Research Council.

Undue Tuberculosis Among Porto Rico Laborers

The laboring classes are reported as suffering an undue proportion of the tuberculosis rate of 200 per hundred thousand in Porto Rico. In the industrial cities on the practically level coast belt the average is about 8 per cent of the total death rate. In the mountainous central portion it is less, averaging about 4 per cent except in certain industrial towns, particularly those dependent upon the tobacco industry. These high rates are not due to the climate, but to working conditions in part, but for the most part to housing conditions, which cause much overcrowding, and to a diet, considered ideal for the propagation of the disease, consisting of black coffee, rice, and beans in great quantities, and sometimes bananas, oranges, and plantains complete the list. The economic status of the average laborer is such that he cannot break the vicious cycle even when proper medical advice is obtainable. The great mass of the people on the islands are engaged in sugar, tobacco, fruit raising, and coffee industries.

Pennsylvania Summer Course in Sanitation

A six weeks' summer course in sanitation is announced by Col. P. M. Ashburn of the Army Medical School at Carlisle Barracks, Pennsylvania, for health officers attached to the state health department of Pennsylvania. The course is a part of a plan on the part of the State Health Commissions of Pennsylvania to appoint all full-time district sanitary officers only from men properly trained in public health work.

Shortage of Hospital Beds for Mental Patients

The annual report of the New York Academy of Medicine announces a marked shortage of hospital beds in New York for the treatment of nervous and mental diseases and emphasizes an intolerable condition of crowding in the state hospitals. The report covers many subjects of interest to public health among which the notable features are: Codification of child welfare laws; the establishment of a hospital information bureau; the collection of hospital statistics; the city's budget in relation to health and hospitals; and matters pertaining to health legislation.

Industrial Workers Evince Interest in Insurance

That industrial workers are taking increasing interest in the protection afforded by life insurance is shown by 1922 figures just issued. The Prudential leads in new industrial insurance for 1922; its total writings being \$631,814,968. The Metropolitan is next with \$563,458,161. The John Hancock has \$196,715,935 and the Colonial of New Jersey \$15,844,747. The Morris Plan wrote in industrial insurance \$6,292,975.

The total new business written by companies licensed in New York was \$6,592,293,742. The total new ordinary and group business of New York companies amounted to \$2,444,640,468. The amount of companies of other states was \$2,823,826,488 and industrial \$324,126,786.

St. Louis City Psychiatric Clinic Assured

The psychiatric clinic inaugurated about a year ago at St. Louis under the auspices of the National Committee for Mental Hygiene was formally taken over May 1 by the Director of Public Welfare, Nelson Cunliff, when it became a city institution. Dr. William L. Nelson has been appointed as chief psychiatric clinic director.

Harrison Act Shows Decreased Use of Narcotics

A recent statement issued by Federal Prohibition Commissioner Haynes in the columns of the *New York Times* indicates that the per capita consumption of narcotic drugs has shown a marked decrease under the administration of the Harrison Drug Act, and refute the statement so frequently made, he says, "that drug addiction and the use of narcotic drugs are on the increase in the United States."

Official figures on imports of narcotics and their distribution showed that sales by manufacturers for the fiscal year ended June 30, 1921, were sufficient for one and seven-eighths grains of morphia per capita, while for the fiscal year 1922 they were reduced to seven-eighths of a grain on a per capita basis. The figures of course were not inclusive of smuggled narcotics. The per capita consumption of cocaine for 1921 was given at one-third of a grain, while that for 1922 was reduced to one-fourth of a grain. The frequent statement that the per capita opium consumption as around thirty-six grains is based, he said, on pre-prohibition statistics.

"There is no country in the world in which there exists a more efficient method of checking the importation, distribution and consumption of narcotic drugs than in the United States under the provisions of the Harrison act," said Commissioner Haynes. "Every ounce of opium or cocaine leaves imported into this country can be traced directly to the ultimate consumer."

Committees Collaborate on Lighting Code

The Federated American Engineers' Association has announced the personnel of a sectional committee appointed to prepare a lighting code for the nation's schools, in collaboration with similar committees representing the American Institute of Architects and the Illuminating Engineering Society. The primary object is to eliminate the waste represented by the faulty eyesight in school children which it is estimated as existing in ten to thirty per cent. The care of the eyes of school children is but an extension of the movement for eye conservation in industry. Louis B. Merks of the Illuminating Engineering Society and Sullivan W. Jones of the American Institute of Architects are in active charge of the committee organization.

The zoning ordinance (No. 922) adopted for the city of Baltimore is published in the May 25 issue of the *Baltimore Municipal Journal*.

Fatigue Research Board Makes Report

The Third Annual Report of the Industrial Fatigue Research Board, London, to December 31, 1922, just issued contains a full account of the work carried out and projected during 1922. In addition, it includes personal contributions from the investigators to the Board dealing with special aspects of the work, namely: "Some conditions concerning Technique," by E. Farmer, M. A.; "The Use of the Sample in Investigation," by May Smith, M. A.; "Some Observations on Industrial Conditions with special reference to Cotton Weaving," by S. Wyatt, M.Sc.; "Atmospheric Conditions and Industrial Efficiency," by H. M. Vernon, M.D.; "Future investigations in the Pottery Industry," by H. M. Vernon, M.D.; and "A Note on Machine Design in relation to the operative," by H. C. Weston, M. J. Inst. E.

Campaign Against Malnutrition Outlined

"The Campaign against Malnutrition" is the title of a report prepared by the Advisory Committee on Foods and Nutrition of the National Health Council in cooperation with the United States Public Health Service, and published as Public Health Bulletin No. 134. This bulletin supplements the general health education program covered in another report and shows where intensive work with malnourished groups belongs in the general health program. The suggestions made are on the basis of nutritional work to suit conditions in a city of 25,000 to 30,000 inhabitants, but the measures are easily adapted to larger or smaller places and an appendix adds data vital to the conduct of nutritional work in rural districts. The staff required, the methods of work, records of progress and results, the equipment of centers, how to secure public support for the work, and the economic bearings of the whole subject are faithfully treated. The educational possibilities of the work are emphasized. The use of this bulletin as a handbook by persons responsible for the health care and health education of children is recommended. The authority of the principles outlined is fully attested by the individuals and organizations represented on the committee, headed by Joseph Goldberger, M. D.

The Dominican Republic will send an official delegate to the Leprosy Congress to be held in Paris this year.

HEALTH PUBLICATIONS REVIEWED

Nutrition of Mother and Child

A book just issued on "Nutrition of Mother and Child," by C. Ulysses Moore, M.D., although it contributes nothing new to this important subject, is interestingly written and should be of value to both professional and lay people.

J. B. Lippincott Company, Philadelphia, 1922.

Laboratory Handbook for Dietetics

This little book, by Mary Swartz Rose, consists mainly of tabular matter for the use of dietitians, chemists, and physiologists. It constitutes a handy reference book. It is technical but not so much that it cannot be used as a reference book by nurses, for which purpose it is recommended.

The Macmillan Company, New York, 1922.

Cerebrospinal Fluid in Health and in Disease

Thoroughness in his treatment of the subject and freshness in his manner of handling it, mark the text of the first edition of "Cerebrospinal Fluid in Health and in Disease" by Abraham Levinson, M.D., and the fact that the book comes so soon to a second edition attests to its value as a contribution. In the second edition many of the older illustrations have been discarded and new ones added. The tabular matter has been completely revised and the chapter on clinical examination simplified. An extensive table is given on the findings of cerebrospinal fluid in various diseases and the bibliography on the subject is brought down to date. The chapter on pathology has been entirely re-written and the technic of cistern puncture has been added.

C. V. Mosby Company, St. Louis, Mo., 1923.

A Study of American Intelligence

In this book Professor C. C. Brigham gives a very clear description of the alpha and beta examinations given to the army draft with an analysis of the significance and reliability of each of the individual tests. He then proceeds to a detailed analysis of the scores made by different racial components in the population as evidenced by the record of a sample group of 15,543 white officers, 81,465 native

born white recruits, 12,492 foreign born white recruits, and 81,465 negro recruits as based on a combined scale in which the three types of examination given receive appropriate rating. The main point which emerges is the marked difference in rating obtained by different racial elements, England, Holland, Scotland, Germany and Denmark rate higher than the native born white draft in the order named. Canada, Sweden, Norway, Belgium, Ireland, Austria, Turkey, Greece, Russia, Italy, Poland and the negro draft rank lower than the native born white draft passing from highest to lowest grades. Dr. Brigham then attempts to reclassify his national groups under the three racial heads, Nordic, Alpine, and Mediterranean, concluding that the Nordic stock is markedly superior and pointing out the effect upon the average mentality of the American population from a replacement of Nordic by Alpine stocks in the immigration of recent years.

Princeton University Press, 1923.

"Rickets," by J. Lawson Dick

Dick's book on Rickets is timely, and the profession is gradually becoming more interested in one of the most common nutritional disorders in childhood. The author handles the subject well and covers nearly every phase of it although it is unfortunate that he leaves out some of the most recent work on the chemistry of phosphorus which has been done in this country as well as abroad. The chemical blood findings in rickets, according to latest research, differ from those in scurvy and the conclusion of this in a system on the treatment of rickets seems very important. The references in the book are not numerous but the author has used good judgment in picking out the most important historical and present-day substantial work. With the exception of blood chemistry it is quite complete, including even the history of the subject. Chapter 25 is of particular interest to public health workers. Chapter 24 states that conditions in slum areas tend to rickets. It discusses the relationship of rickets to the national health as well as in the army recruiting records. The author limits his statistics to England, which

is expected from a British author. Some of the theories regarding food factors in rickets might be challenged by people who are engaged in research on the subject. As a whole, however, the author holds to most of the acknowledged views on the subject.

E. B. Treat & Co., New York, 1922.

Pirquet's System of Nutrition

In this small book of 96 pages, a Professor Clemens Pirquet gives a summary of his new system of nutrition which was originally published in Germany in four volumes. As is well known, the author bases his system on body measurements especially the sitting height. He has also done away with the use of the calorie as a unit of theme and has substituted the nem for it. A good deal of criticism has been hurled against this Pirquet System and there is no doubt but that in this country the Pirquet System would not apply itself as easily as in Austria. The author must, however, be given credit for his ingenuity, for his accuracy, and for the diligence with which he worked out his system of feeding. Pirquet has been able to feed hundreds of children by means of this new system and seems to have accomplished a great deal.

The book also contains a chapter on treatment of tuberculosis and another chapter of feeding as preventive medicine. It also contains an extensive bibliography on this new system. It is a veritable treasure of information for anyone interested in the newer trends of feeding.

W. B. Saunders Co., Philadelphia, 1922.

Getting Ready to Be a Mother

This book follows closely the previous work of Carolyn Conant Van Blarcom on obstetrical nursing. As in the first book, a great deal of information is imparted by the author in simple language. The illustrations add materially to the book. It is interesting to note that the author has left out a discussion on accidents in pregnancy so common in other books. This omission will do away with the mental anxiety produced by discussions on accidents. It is one of the few books that can safely be handed over to an expectant mother.

The Macmillan Co., New York, 1922.

History of the National Tuberculosis Association

The author of this book filled a vacant space in American medical history as there has been no treatise incorporating a contribution of American medicine in the history of tuberculosis. Although he has limited himself to the story of the National Tuberculosis Association, the book throws light on the life and work of many outstanding figures in American medicine. The personal touch added to many biographies in the book makes its reading of still greater interest. The author was entirely too modest in omitting his own biography. Many a reader would have liked to find out the life history of so interesting a writer as is Dr. Knopf.

National Tuberculosis Association, New York, 1922.

The Health Speaker's Handbook

This little booklet of fifty-two pages is a manual of the technic of health propaganda from the platform, published by Iago Galdston, M.D., secretary, industrial and speakers service of the New York Tuberculosis Association.

The subjects dealt with include the training of speakers; the selection of pertinent and suitable lecture material from the vast amount of material available on health matters; the selection and use of literature, charts, slides, blackboard drawings, and moving pictures; the adjustment of such materials to the spoken lecture. Considerable emphasis is placed upon the industrial worker's need for health education, and the approach to him through the shop and through the union, and the adaptation of materials to appeal to men in the different trades.

An appendix contains a number of outlines organized about tuberculosis and adapted to various audiences.

New York Tuberculosis Association, 10 E. 9th St., New York City.

Eating Vitamins, by C. Houston Goudiss

This is a very pleasant little dose. It contains the interesting story of the development of our knowledge of the accessory food factors served in popular cafeteria style and well garnished with illustrations of famous men like McCollum, Funk, Hopkins. As side dishes are photographs of famous "calves of destiny," and of delectable articles of food like cabbage, oranges, turnips, eggs, liver, and milk. Menus and recipes rich in vitamins form more than half the book: as we read, we wonder what has become of the

formerly well-known calorie of which we used to hear so much.

The value of a book like this depends entirely on how much the reader knows about the other important constituents of food. It is probably a truism to state that even vitamins have only a relative importance in the normal dietary, and that eating vitamins, like eating calories, is only one part of the day's nourishment.

Funk & Wagnalls, New York & London, 1922.

Syphilis As Affecting the Innocent

A recent study of the social effects of syphilis on the family and the community, by Harry C. Solomon and Maida Herman Solomon, is a valuable addition to the literature of syphilology especially for the layman interested in the implications of this disease as effecting our social structure.

Congenital syphilis is always syphilis of the innocent. "The saddest part of syphilis is that it is transmitted to the second generation." A brief description is given of the "Hospital Schools" of Europe, established for syphilitic children, where treatment, excellent care, and education are carried on simultaneously. The United States is sadly lacking in this respect. "Many people erroneously feel that if a child has seemed to escape without early symptoms (often present but undiagnosed) the danger line has been passed, but the symptoms of congenital syphilis may appear at any age in babyhood, childhood, early or late adolescence, or even in adult life."

This work also gives much valuable information on the relation of syphilis to blindness. Syphilis needs the same careful consideration now given to gonorrhea as a cause of loss of vision.

The cost of syphilis to the community is appalling. For the writers' own state, Massachusetts, it is approximately \$225,000 annually. Less than 10 per cent of this is expended for prevention while over 90 per cent is used for the maintenance of patients who have passed the stage in which help is available.

To the sociologically inclined reader the book is of much interest. The method of treatment is scientific, and the conclusions are reasonable and the recommendations possible of execution. The book will be of assistance in furthering public and private action that there may be an adequate attack made on the scourge of syphilis.

Social Work, an Outline of Its Professional Aspects

A small thirty-one page pamphlet called "Social Work, an Outline of Its Professional Aspects," describes briefly, yet comprehensively, the various lines of activity open to the social worker, telling the sort of training necessary for work along each of these lines.

In this booklet, recently published, the different kinds of social case work which have developed in the profession, including work with families, with children in and out of the schools, with delinquents, and with the physically and mentally incompetent, are adequately reviewed. Paragraphs are devoted to the comparatively new branches of occupational therapy and psychiatric social work. There is a chapter dealing with social group work, such as settlement club work, independent club work, and work in the Christian associations. The section devoted to community organization is especially interesting and informative, embracing as it does, rural organization, health organization and education, economic organization and development, housing, leisure time activities, and neighborhood organization.

The book also contains information regarding institutional work, psychological work, personnel work in industry, work with racial groups, public health nursing and nutrition work, besides that very important branch of social work known as social research. There is a list of training schools which are members of the American Association of Training Schools for Professional Social Work—and a short paragraph on salaries paid in the social work field.

School Architect's Problems

(Continued from Page 416)

interest of the pupils can take the place of a swimming pool and where installed should be equipped with good filters, a sterilizer, and with a vacuum appliance for removing sediment and lint.

One of the most troublesome features in school buildings has been the construction and finish of class room floors. The corridors and toilet rooms have been satisfactorily floored with tile or terrazzo and where properly laid these flooring materials have proved very satisfactory for the purpose. These materials are too hard and cold to be used for class room floors. The use of wood floors has always been objectionable on account of dust, noise, and the gathering of dirt in the cracks. To overcome the dust problem the practice of oiling wood floors has been extensively tried out but this has a number of disadvantages and is not sanitary. This also leaves unsolved the problem of the dirt that gathers in the cracks. To a certain extent the use of the vacuum cleaner overcomes these difficulties but the ideal floor should be a continuous surface without joints or cracks, should be a moderate non-conductor of heat and should be quiet and easily cleaned. There have been a number of methods tried out with very fair degree of success using either composition, mastic, or battleship linoleum. Each of these floors is laid directly on the concrete slab, if the building is of fire-proof construction. The various composition floors are laid approximately one-half inch thick and are spread over the surface practically in the same manner as concrete is laid, with a cove and base formed at the walls of the same material, thus eliminating not only the wood flooring but the wooden base. Where properly laid over good material this makes an ideal sanitary floor. The mastic flooring is laid in the same manner except of approximately $\frac{1}{8}$ inch or $\frac{3}{16}$ inch thickness instead of $\frac{1}{2}$ inch. The mastic floors are somewhat warmer under foot and are slightly quieter but do not have quite the same firmness nor smoothness of surface. Battleship linoleum is the most recent material used for school floors and, where properly laid, makes an ideal floor material.

In any case it is desirable that all school floors should be cleaned daily with the vacuum cleaner but the use of these types of floor finish greatly

reduces the amount of dust as the elimination of the joints and cracks in the boarding does away with the reserve of dust these always present to be stirred up with every footstep.

Where the advantages to health and interest as above sketched are properly supplied in the modern school, experience shows that the pupils look forward with more eagerness to at-

tending such a school and are more happy in the enjoyment of all of its mental and physical privileges.

The illustrations used in connection with this article have been taken from the Benjamin Franklin Junior High School building of New Castle, Pa. This building has attracted a great deal of favorable comment especially with reference to the features mentioned in this article and has been selected for illustration for the reason that it is one of the latest and possibly one of the best equipped of the recent public schools.

Milwaukee Weekly Cardiac Clinic

THE weekly cardiac clinic at the Out-Patient Department of the Milwaukee Children's Hospital was established more than three years ago. At the outset it was deemed essential according to Dr. Malcolm F. Rogers, director of the clinic, that the decompensated case be put back in a compensated state. Soon the idea of keeping the child in the best cardiac condition possible came to the at-

the condition of the individual case.

At first entrance a complete physical examination is made, supplemented by a special cardiac analysis, including (1) history of complaint, (2) previous illnesses bearing a possible etiologic relationship to any existent cardiac disease, (3) special cardiac examination including electrocardiographic and oftentimes x-ray and fluoroscopic work. Blood and urinary analyses are routine.

The staff is constantly on the watch for infections of teeth and tonsils, for chorea, rheumatic fever, and syphilis. It is the general policy at this cardiac clinic to treat all suspicious foci of infection as being positive. Dental caries and tonsillar involvement are not tolerated; choreics and rheumatics are promptly hospitalized.

As soon as the cardiac is discharged from the hospital, he again reports to the cardiac clinic. Week after week the cases are gone over with the same thoroughness. Notations regarding the number of hours of bed rest, the amount of exercise taken, and the individual's ability to tolerate the same are tabulated, together with a history of infections encountered. An accurate record of weight variations with suggestions as to dietary and general hygienic improvements is kept. The children, divided into small groups, are given graduated exercise at each visit. The services of two Junior League members, who give their time to this course, Miss Florence Patton, having charge of the medical follow-up work, and Miss Joy Shadbolt, director of graduated exercise classes, have been of great value in the work being carried on by Dr. Malcolm F. Rogers.

The heart patient, no less than the normal child, thrives on exercise. The only difference is that the activities of the cardiac patient must be precisely regulated and continuously supervised.

tention of those in authority and the organization was enlarged to meet a constantly increasing demand.

At the present time children report weekly, bi-monthly, monthly or at least every six months, depending on

Recreation in Hospitals and Its Therapeutic Values

(Continued from Page 479)

wholesomely adjusted themselves to institutional régime. Many chronic cases of long standing have been so greatly improved through recreational-occupational activities that they have been sent on to definite constructive work in and about the institution. Only a few weeks ago in one of the large eastern hospitals several men who had never before during their stay at the institution been capable of doing any sort of work were taken from one of the occupational-recreation classes, where it was felt that a certain gain had been made in stabilizing their reactions, and were placed in one of the work squads shoveling snow and cleaning roads. At last reports they were working comfortably with the other patients in the squad. The whole scheme of reeducation, occupational training and recreation is definitely planned to lead through various grades of progress into practical vocational activity, in-

side of the institution for those whose improvement is sufficient and outside for those who having made greater gain are deemed eligible for parole.

With the other large group of mental cases, the mental defectives, there has been for years recognition of the training and socializing values of organized play. Alexander Johnson⁴ tells in his recent book of the large place which was given to recreational activities in this work in this field in Indiana. The mental defective needs two primary types of training; for individual competence and for social adjustment. The great majority of the mental defective, especially if they are given special care when they are young, are capable of a certain

amount of development. The older and more conventional attitude is to accept their condition, to say that they are incapable of training, and that therefore they should have permanent custodial care. This is doubtless true of many of them, but on the other hand the child who though incapable of great progress can be, through a course of training extending over a number of years, brought from a mentality of approximately eight years, which would otherwise be his permanent mental level, to a men-

sults. Here, as with the insane, it is very essential that the work be made interesting and appealing and this is best done by giving it a recreational aspect through appeal to the fundamental play instincts of childhood.

From the standpoint of the socialization of the mental defective, play activities make a large contribution; untrained their individualism runs riot, but with proper training they can be fitted into the society of which they are a part. If of lower mentality they will continue in the institu-

tion, or if having shown sufficient improvement they go out to take their place in the world as "hewers of wood and drawers of water," in either case they will have a more normal recognition of their relations to others because of the social training they have received through play. We have only to recognize how large a part play contributes to the formation of our fundamental ethical-social concepts to realize the value of play

Work in the wood-working class is play because the desires of the child are followed as far as possible in what he undertakes to make. Note the toys on the cupboard at the left and on the window bench in the center. Hundreds of toys are made by the children at the Vineland Training School each year.

tal age of ten or eleven years has, while gaining but little, really attained a great deal because he has passed from the level of incompetence to one of greatly improved personal ability. The difference between an eight year mentality and one of eleven years is vastly greater, as a measure of individual competence, than it seems to be upon mere casual thought.

It is not necessary to enter here upon an extended discussion of the validity of the classification according to the two types of intelligence, the verbal and the manual. The institutions which care for mental defectives are finding that such intelligence as their wards possess is largely of the manual type and the training provided, being almost entirely of this sort, is showing some remarkable re-

sults in socializing mental defectives. It is almost entirely through play that we, all of us, regardless of our mental ability, learn loyalty, team work, self-control, respect for authority, and in fact almost all of our social ideals.

The story is told at Vineland Training School of a lad of sixteen with very low mentality who was brought there by his parents, people of wealth and culture. He fitted into the régime very readily and proved a good patient in every way. When he had been there for some months his father visited the institution. Going to the office, he received a very favorable report from the superintendent, but requested the privilege of visiting the boy while at his work. Unannounced he went to the dairy and found his son busily scouring aluminum pans

4. Johnson, Alexander: *Adventures in Social Welfare*, Part 3.

and buckets. His father asked him if he wanted to go home and, receiving an emphatic negative, he asked the boy why he liked the school. The boy replied, "I have a fine job here. Don't you think my pans look bright and my room is all in good order?" "Yes," said the father, "I do, but do you work all the time?" "Oh, no," the boy answered, "We play a lot, and I have lots of boys my own size to play with and we have fun all the time."

When alone with the superintendent this father stated that he had spent thousands of dollars and infinite pains with the boy but had never seen him happy before. "Now," said he, "he is happy. He has found work that to him is interesting, companions that are congenial and has fun all the time. For the first time in years I am content. I want my boy to stay here."

This story is in its essentials being repeated wherever progressive men and women are using interesting work and wholesome play as a means of training those who live in perpetual childhood.

Recreation is making a real contribution to the care of those who are fighting tuberculosis in hospitals and sanitariums. A very definite technic has been worked out for these institutions and those who are most progressive are recognizing the necessity for wholesome interests and activities to tide over the period of convalescence. This is the most difficult time with the average patient. As he begins to improve and to build up the reserve of strength which is necessary for the final victory over the disease he becomes more and more restless in his enforced idleness. At the best of the institutions the discipline in regard to long periods of rest is of course rigid, but combined with this there must be certain diversions and physical activities if the patients are kept in such mental condition that the greatest good may be expected from their treatment. Many a patient in a sanitarium has suffered a relapse through his restlessness or through the homesickness which found a fertile field for growth in the lack of wholesome interests and activities. It is certain that any games or activities of any sort that are undertaken at a sanitarium must be carefully supervised, and be under the direct and rigid control of the medical officers, but in many such places today very wholesome recreational activities are being conducted.

At a large sanitarium in the Adirondacks last summer the writer saw several hundred convalescents sent off in

mid-afternoon for an hour's walk. The great majority of them started along a state highway for a leisurely stroll and as soon as they were around a bend out of sight of the institution perched like black-birds on a hundred yards of white railing, which defined a long sweeping curve in the highway, and there they sat during practically all of their hour's "walk." Certainly they were in the open air and the highway furnished a change of scene, but it would have been much better for their minds and their bodies had there been someone in the institution charged with a definite responsibility for planning for these daily walks.

The possibilities here were more pronounced since it was a country where an abundance of historical and scenic interests were available within a very short distance, and one could not but feel that the broad lawn under wholesome leadership might have been utilized for bowling greens, croquet courts, and putting greens, and a whole series of contests organized both individually and in teams, extending for weeks the intensive interest and activity, and furnishing not only opportunity for occupation of mind, as well as of body, but also for a large amount of conversational material and argument to occupy the thought and attention of spectators, as well as participants.

At this institution occasional dramatic and musical entertainments are produced by the patients, and one of the staff with whom I talked, expressed to me most intelligently and enthusiastically the appreciation of the possibilities which had been discovered through the little which had been done. No single contribution to that institution with its hundreds of patients could be greater than that which could be made by placing on the staff of the hospital a person with practical experience in recreational activities, who could give constant thought and organizing ability to the task of providing a wholesome, varied program of games, music, entertainments, dances, and of promoting every activity and interest that would normalize, stabilize, and broaden life for these patients. The same opportunity exists in a large number of sanitariums.

Opens a New World

A notable example of wholesome recreation is found at three hospitals in and near Pittsburgh where a complete wireless equipment has been installed in each. A patient who has a great deal of skill in handling wire-

less equipment has personally supervised the installations. In the three institutions between three and four hundred beds are equipped with ear phones so that at almost any time, day or night, a patient can reach out and, securing a conveniently suspended receiver, place it to his ear and be in touch, as long as he wishes, with the great world outside, hearings news, sporting and business reports, and music of all sorts from widely scattered points. One of these institutions in Pittsburgh "has been listening in" on New York, Schenectady, Detroit, Washington, and Chicago, as well as on two stations in Pittsburgh. The mental stimulus and emotional appeal of this sort of thing is of great value, and by means of the individual phone, which has proven much more popular than the amplifier, each patient is allowed to participate as little or as much as he desires in this sort of activity.

In the hospitals that are taking care of the physically handicapped, recreation is accomplishing a work that has large practical and sentimental values. No more stirring experience can well be imagined than that which comes when one sees a serious and intense group of men and women who are dealing with an institution full of crippled children as they plan and debate the adaptation of all sorts of games to the capabilities of their maimed and disfigured wards. Many of the devices which have been introduced and means which are taken to bring real, joyous play to these hopelessly crippled individuals are really thrilling. Of almost equal appeal is the work that is being done for the deaf and the blind, and all sorts of devices have been arranged so that they may play regardless of their handicaps.

The value of the type of recreation that these handicapped people are getting cannot be overestimated. One of the most serious phases of such a condition is the "inferiority complex" which the handicap creates in the mind of the individual. A boy or girl facing life with this idea in the background of the mind has often a more serious burden of his own creation than that which nature or accident gave to him. Often it is possible upon the play field, in the gymnasium, or even in the wards, for him to measure his mental alertness, strength, agility, or skill with his fellows, and competition with those who are normal in every way, is particularly valuable, not simply for the development of individual ability but for over-

coming the feeling of inferiority.

A school for the blind in Michigan had last fall the unique distinction of being represented on the football field by a team which made an excellent record. This team was made up of four boys who were totally blind and seven with partial vision. They played regular intercollegiate football with no modification of the rules, against teams representing the high schools in neighboring communities. Those who saw the games report an excellent quality of football and a wonderful influence upon the boys.

In hospitals that are handling general cases there is a large opportunity for recreational activities. While a great majority of the patients are there but a short time, in every such institution there are people who spend long months of dreary confinement. The institution which recognizes to the fullest extent the human element in its clientele is making a definite provision for recreation for such people. These activities range all the way from dolls and toys for little children to program and entertainment and even active participation in music and simple games by the patients.⁵ Here again recreation is contributing much, not simply from the standpoint of corrective physical activities, but it also means much to the mental condition of individuals who are there as patients.

There is a secondary value in this whole subject which must not be overlooked. Those who are dealing with the general public cannot fail to recognize the attitude which many people still maintain toward the hospital and all similar institutions, and the readiness with which any charge of cruelty or mistreatment is accepted without thought or regard to evidence. The background for this attitude is of course one of ignorance and misunderstanding. It is rather difficult to provide popular education as to the technical aspects of hospital care, and to make people realize that in the great majority of cases of abnormality or sickness no other care can possibly be provided that will be as effective as that of the hospital, but excellent educational opportunities are offered by emphasis upon the human side of the hospital and no aspect of its work so readily appeals to people at large as recreation. The moment we convince the general public that the old "asylums" with prison discipline no longer exist, that in their

place we have modern hospitals, whose patients are happy and contented, popular ignorance and misunderstanding, the materials upon which "yellow" journals fatten, will disappear.

A visit to a large hospital for the colored insane in one of the southern states brought out the fact that out of two thousand five hundred inmates only four were on that day under any restraint of any kind. After spending a day at the institution and seeing the remarkable results being achieved in the way of contentment and happiness, the question was asked of the superintendent, "How do you do it?" The whole spirit of the place was embodied in his laughing, laconic reply, "Watermelons!"

At an institution for mental defectives with six hundred patients, a happy contented group, the question was asked, "What is the best description of your methods?" and the reply was, "This is simply a great kindergarten." At another institution for mental defectives with two thousand two hundred patients it was reported at a staff meeting that for forty-eight hours there had been no disciplinary problems of any sort. In answer to the question as to how it was accomplished the superintendent said, "Our children play."

When we can make people understand that recreation and wholesome occupations are helping the insane by improving their physical and mental condition and affording at least some hope of their permanent improvement, that we are making our institutions for mental defectives great kindergartens, that we are breaking down the monotony of life at the tuberculosis sanitarium, and that we are helping the sick and those suffering from physical disabilities to win their fight against handicap and disease as well as against their own feeling of loss and failure, we will gradually begin to see a changed attitude on the part of our public.

Where recreation is being used in such institutions it is proving of great value for constructive publicity. It is much better for the metropolitan journals to carry a half page write up, with photographs, of the outdoor production of *Midsummer Night's Dream* by two hundred blind children, as was done in Philadelphia, than it is for us to allow our only publicity to take the form of scare-head reports of investigations which emphasize and exaggerate the mistakes and failures which will occasionally occur even under the best and most careful institutional management.

Recreation affords a constructive

approach to the patient in the hospital and also a constructive approach to the rank and file of people whose intelligent interest and support are necessary for any permanent progress.

Trachoma in the United States

At the twentieth annual conference of state and territorial health officers with the United States Public Health Service, Dr. John McMullen, secretary of the standing committee on trachoma reported on the progress of trachoma work in this country.

The general work included 27 clinics in rural communities at which more than five thousand people were examined, and 686 cases found. Four hundred and ninety-eight operations were performed, 158 being done under general anesthesia. The majority of the clinics were in Kentucky; others in Ohio, Texas, Mississippi, Tennessee, and North Carolina.

The most prominent piece of trachoma work done, according to Dr. McMullen, was a clinic conducted in south Georgia, by the service which furnished the medical officers and two nurses. The county furnished the building which was a small modern hospital that had proved a financial failure. The clinic was conducted from November 14, 1921, to April 1, 1922. The total attendance was over 3,000 the trachoma cases nearly 300, and the operations 381, not all of the operations being on trachoma patients. At the request of the state health officer, local doctors, eye specialists, and the county commissioners who paid the bills, persons suffering from conditions other than trachoma were admitted to the clinic.

The discovery of trachoma in this region was something of a surprise to the authorities who, at the request of the state health officer, made an investigation and found conditions much like those that have long existed in eastern Kentucky and Tennessee. The origin of the disease could be traced back four generations, where it was lost. Entire families were found to be suffering from trachoma. Not a few of the infected had lost their sight entirely and even more had lost the sight of one eye.

Dr. McMullen's report is contained in the transactions of the Conference, Public Health Bulletin No. 128.

Public equipment for recreation in Detroit includes sixty tennis courts, thirty-six baseball diamonds, sixteen swimming pools, eighty playgrounds, and one Bowling-on-the-green-court.

5. A pamphlet which has been issued by the Chicago Training School of Recreation, 800 S. Halsted St., Chicago, Ill. "Hospital and Bedside Games," by Neva L. Boyd is based upon very practical activities of this sort and will furnish an abundance of material for this sort of work.

KOTEX

A most convenient vacation item

WOMEN now take a supply of Kotex on their holiday trip. Kotex are included in the personal baggage of the American woman on trains, motor cars, and ships—everywhere. On a journey away from shopping centers they may be considered indispensable.

There is no other sanitary pad so easy to dispose of, so inexpensive, so safe, so cool and comfortable or so easy to buy—and no other pad is made with Cellucotton, the wonderful absorbent science has recently perfected for our use.

If the vacation is to be spent in this country or Canada within reach of stores that serve women, it is easy to buy Kotex. But it is a great convenience to have Kotex *instantly available* when traveling just as at home.

Ask for them by name.

Sold everywhere in Dry Goods, Department and Drug Stores

Copyright 1923, Cellucotton Products Co., 166 W. Jackson Boul., Chicago; 51 Chambers St., New York City.
Factories at Neenah, Wis. Canadian Office, No. 45 St. Alexander St., Montreal.

Regular Size, 12 for 65c
Hospital Size, 6 for 45c
(Additional Thickness)

Kotex cabinets are now installed in women's restrooms everywhere—hotels, office buildings, restaurants, theatres, and other places—from which may be obtained the Kotex which you are in need of, in plain wrapper, for 10 cents.

Home-Making Experts Attack Problem of Cincinnati's Housing

(Continued from Page 421)

of the minimum of conveniences in homes, to help them with the economical expenditure of their budgets and with matters of cleanliness and order in the home. They teach tenants how to make inexpensive articles that add to the attractiveness of their rooms. They encourage the making of gardens, the planting of flowers and in general do what they can to add those touches that give some suggestion of real home life.

This is only one part of their work.

After having been in touch with the tenants in a house and having made a beginning in their instructive work, they go to the owner of the property, tell him what they are doing to help improve his house, how they are trying to persuade tenants to cooperate with him in keeping his building in good order, how they are trying to help tenants to regulate their budgets in such a way as to pay rent promptly. In return they ask him to make

such improvements in his house as may appear to be necessary. From time to time they encounter an owner who is absolutely unbending, who has no use for social service in any form, but thinks he knows his own business far better than we do and will give us no degree of cooperation. In such cases we have recourse to the enforcing powers of city departments. It is gratifying, however, that in nearly 75 per cent of the cases we are able to get some degree of cooperation. At times the cooperation is remarkably effective, at other times it is much less satisfactory. Likewise there are times when we encounter tenants who are so degraded because of addiction to drink or drugs, because of delinquent tendencies or because of some mental abnormality, that we can get

no cooperation from them. Rarely, however, do we fail to accomplish some results either with tenants or owners.

With a problem like overcrowding, which is so frequent now with the shortage of houses, we have found no other way as effective as the visiting housekeeper method. When we find four, five or six people to the room, as is not at all infrequent, we try to persuade them to move to larger quarters in case they are able

to find a decent place to live. We have refused help in no case where there has been any hope of our being able to provide relief.

In order to make our message more concrete the League has established in the West End colored district, where the worst housing exists, a House-keeping Center. It consists of three typical tenement rooms fitted up in the simplest possible way, neat, orderly and attractive, yet so inexpensive as to be within the means of the ordinary family. Here

in this little three-room flat we try to show mothers and girls by actual example how they can make cozy rooms in a typical tenement. During 1922 this instruction reached 823 mothers and girls and we conducted nine classes in housekeeping with a total attendance of 175.

An interesting effect on the visiting house-keeper work has been the minimizing of the bad housing conditions among the foreign-born. A

few years ago there were many cases of overcrowding and there was much bad sanitation and bad housekeeping among our foreign-born population. Due to the restrictions on immigration we have had some opportunity to catch up and have made real progress in instructing these people in American ways of living. In addition, as a preventive measure, four organizations are cooperating in meeting the immigrant families coming into this city, acquainting them with the requirements of our health regulations, helping them find suitable housing accommodations and putting them in touch with agencies that will help them to understand America and its institutions. The Travelers' Aid meets all immigrant families as they come into the city, takes their names and the

Terraced slopes showing individual effort and community pride now grace the approach to these hillside homes. This is a fine example of the growth of an idea

to afford it. When they are too poor to pay for enough rooms we try to have their income supplemented by family relief agencies. Right now, however, with the supply of tenement houses actually less than it was two or three years ago, the problem of overcrowding is becoming constantly more perplexing and our efforts will be less and less effective because of sheer lack of sufficient housing accommodations unless the pressure is relieved by the construction of homes at a very rapid rate.

The acute shortage has made it necessary for the League to permit its visiting housekeepers to devote a large part of their time to finding homes. Our offices have been besieged during the past year and a half by mothers exhausted in their ef-

For You— Pleasant Days of Cool Comfort

COOL, comfortable feet permit restful relaxation on hot Summer days. They leave your mind free to enjoy delightful outings and add to the recreative qualities of your vacation.

Cantilever Shoes give the feet free play and wonderful comfort. Swollen, uncomfortable feet caused by retarded circulation, are liberated in Cantilever Shoes. The arch of the Cantilever Shoe, flexible like the arch of your foot, curves up when the shoe is laced to follow the exact contour of the under foot. This gives gentle, helpful support to your arch without restraining its muscular action. Your foot muscles are allowed to strengthen, through exercise and weak arches are corrected and prevented. Circulation is free.

The natural lines and moderate heels of the Cantilever Shoe permit your foot to be comfortable, as Nature intended. Your toes have room to straighten out. There is no binding anywhere and your foot feels at home and at ease.

Cantilever Shoes are made of fine soft materials that are easy on the foot and pleasing to the eye. These shoes are trimly proportioned and in keeping with this season's styles.

Women have discovered that restful Cantilevers give them the knack of appearing cool and attractive during the warm weather. They have learned to make Summer a season for ease and comfort and to accomplish more without fatigue. In nearly every city in the United States there is a Cantilever Store where you will be carefully fitted by men who understand the requirements of your feet.

Except in New York City and Chicago there is only one Cantilever Store in each city. At the left is a partial list of the stores that have been selected to sell Cantilever Shoes. If none of these is convenient, write the manufacturers, Morse & Burt Company, 15 Carlton Ave., Brooklyn, N. Y. for the address of the nearest dealer and a new booklet on feet and shoes.

YEAST

—a natural stimulant of intestinal activity

With increasing recognition of the deficiencies of concentrated, artificial modern diets, has come increasing use by the profession of fresh yeast as a valuable dietary supplement.

While in no sense a substitute for proper exercise or fresh vegetables, Fleischmann's Yeast does act as a natural stimulant of intestinal activity.

"Three cakes per day" concludes the report of a recent test on some 85 subjects, "improved the condition of every individual who had any degree of constipation."

Not only does Fleischmann's Yeast assist regular intestinal activity, but its vitamin content is

highly beneficial, and experiments have shown that it also helps to produce a definite leucocytosis.

Best results are obtained by eating one cake half an hour before each meal, or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk, or fruit juices.

A new authoritative book: written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry, and therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing The Fleischmann Company, Dept. Y-21, 701 Washington Street, New York, N. Y.

address they are going to and submits this to the board of health. The board of health examines the family to detect any communicable disease, makes the proper recommendations and refers the card to the Better Housing League. The League makes a study of the home condition and through the visiting housekeeper gives such advice as is needed. The card is then passed on to the Americanization committee which places the immigrant in touch with ways of learning English and other things they should know to fit themselves into the city's life.

That the visiting housekeeper plan accomplishes results is shown in the accompanying illustrations. It is shown also by our records of the work done. During the year 1922, our visiting housekeepers made 8,939 visits to families and succeeded in making some improvement in house-keeping conditions in 589 families. They inspected 907 houses, made 3,227 reinspections to improve housing conditions; interviewed 1,371 owners; had 5,538 bad housing conditions remedied; had parts of houses cleaned and painted in 4,459 cases; rooms and halls papered in 788 cases. The visiting housekeepers visited and aided 107 immigrant families that came into the city during the year; and found homes for 260 families.

Plan Garden Village

The task of trying to insure that all houses in a community shall be fit places for people to live in is one of the most difficult. It runs up against economic prejudices. It is blocked at the present time by high building costs. It must grapple with the difficult job of trying to unmake mistakes of the past. Cincinnati has made some progress for which we are grateful. We still face a problem so great as to check any undue optimism.

There is one particularly bright spot in the future outlook. It is the model town of Mariemont, a great project by one of Cincinnati's public-spirited citizens, Mrs. Mary M. Emery, who has undertaken to construct a garden village on the outskirts of the city. This plan calls for the eventual development of approximately one thousand low-cost homes. They will be provided with churches, schools, library, community house, parks, playgrounds, and all things that go to make up an ideal community. It is all to be carried out along the most modern city planning lines. Those in charge of the project have studied the successes and failures of other efforts both here and abroad

and are employing the most skilled minds available to guide the project along sound lines. There is every reason to look forward to what will be one of the most satisfactory efforts along this line ever undertaken in this country. We have every confidence that it will mean a great step forward. It will set a standard which we believe will put its stamp upon all low-cost home construction in the city. We hope it may even provide some inspiration and help for other communities.

It is particularly interesting that Cincinnati should be fortunate enough to have such an ideal housing development in prospect since we happen also to have one of the most interesting and successful low-cost housing developments completed before the War. This development was undertaken by the Schmidlapp Model Homes Company under the guidance and inspiration of the late Jacob G. Schmidlapp. The development consists of small multiple family houses with about four hundred apartments renting at an average of four dollars a room per month, some increase over their original rentals, but nothing like what has taken place in most tenements. They are well planned. The rooms are of good size, they all have plenty of light and ventilation, each flat has its own bath and toilet. The houses are remarkably well maintained. It is significant that while tenement rentals in Cincinnati for even the poorest accommodations average \$5.50 a room a month, yet the Model Homes Company is renting its flats, which are incomparably better than almost anything else we have in tenements, for so much less. At the same time the company has continued to earn 5 per cent on the money invested. They have refused to increase their rentals in proportion to the rents prevailing generally. Several efforts have been made within the past year and a half to try to figure out ways by which it would be possible for them to build more homes under existing conditions. They have found it absolutely impossible, however, to build any kind of house that can be rented for the present rents in their existing houses and they have preferred not to build rather than to have to make further increases in rents.

International Mental Hygiene

From 1909 to 1918 the United States was the only country having a national organization for mental hygiene. As is stated in the *Mental Hy-*

giene Bulletin for January, 1923:

Comparatively few seem to realize that the mental-hygiene movement is now international in scope. National committees are at work in the United States, Canada, and South Africa. There are leagues for mental hygiene in France and Belgium. During the past year in Great Britain a national council for mental hygiene has been organized, and the forerunner of a national committee in Australia has taken form as a section on mental hygiene in the Australian Public Health Association. Plans for organizing a national league, or council, or committee are under way in Italy, Spain, and Brazil, and the situation is such in a number of other countries, among them Holland, Denmark, and Norway, that similar agencies can and no doubt will be established within the coming year.

Today the International Committee awaits only an appropriate occasion for its formal founding. This will doubtless be accomplished at the First International Congress on Mental Hygiene which according to present plans is to be held in the United States early in June, 1924.

Catching Colds by Hand

H. W. Hill, Director of the Institute of Public Health, London, Ontario, said in a radio talk broadcasted by the New York State Department of Health, that 90 per cent of infectious diseases are spread by the hands. To the scoffer who asks how colds are spread in this way this reply is made.

How? Well—think. You have a cold; you sneeze; to prevent your mouthspray from flying, you cover your nose and mouth with your hand; so far, so good. Then—you shake hands with your friend—and the mouthspray which you saved him from getting through the air you give him on your hand! "But it won't hurt him on his hand?" No—not while it stays there—but watch him—in a minute he has his fingers in his mouth or on his lips or he pulls out some chewing gum with his fingers or picks up his pipe by the stem and puts the stem in his mouth.

"But I don't sneeze on my bare hand—I use a handkerchief to keep my sneezes to myself!" Good—then you put your handkerchief in your pocket—presently you pull it out again; and where do your fingers go this time? Right on the very place on the handkerchief where you sneezed the first time!

New Orleans through its *Municipal Health Bulletin* credits the marked improvement in infant mortality rates in 1923 over the same period in 1922 to the improvement in the city's milk supply, the ratio in gastro intestinal disease having markedly decreased. The entire increase in these deaths, is due to respiratory disease.

Protection of the Working People of Belgium

(Continued from Page 425)

normal length of eight hours with certain limitations and compensations that are too numerous to list here.

(2) It will have been noted, in the short review of the compensation law given above that if it forces the employer to pay the treatment expenses, it in no way compels him to provide first aid to the injured. There was, it is true, a royal decree antedating the law itself, imposing a measure of this kind, but its provisions were not very practical, the conditions imposed being vaguely defined and the punishment provided depending on evidence that the lack of care resulted in bad consequences for the injured. The government thought it had to make further steps in this matter, and a complementary royal decree (Royal decree of June 17, 1921) orders measures which, in substance, are as follows:

The employer is obliged to make provision that all serious pathological cases (accident or grave indisposition) occurring at work, receive promptly adequate medical care. He must also put at the disposal of the patient a convenient temporary shelter, and have him comfortably conveyed to the nearest relief place. But the royal decree is not limited solely to this general provision; it also forces the employer to keep ready at any moment, for the use of the wounded, a minimum first aid equipment; these varying according to the importance of the factory and the special risks of the industry.

Moreover, in all cases, where more than twenty-five people are at work, a special room must be kept, exclusively for the care of the wounded. This place must be furnished according to the stipulations of the decree.

This last provision may seem rather strong and little justified by the real needs of the industry. But it has only been formulated in order to induce the manufacturers to organize suitably their methods of assistance. In fact, it is mitigated by a disposition according to which one may be exempted provided one has made sure, by a previous contract, of the assistance of a medico-surgical institute approved by the Minister of Industry and Labour and situated within the radius of twenty-five kilometers of the work place.

Of course this approval is granted only when those medical institutes present a minimum of favorable conditions. The principal conditions are: convenient medical machinery, the possession of telephone connections, and of improved means for conveying the wounded.

By these methods, the government realizes a double aim: to assure, throughout the kingdom, to all injured workers, quick and convenient medical care; and to create, by this control, an advantageous rivalry among the various hospitals.

At this moment, the results are most encouraging. More than four industrial firms have obtained exemption from the provision requiring a first aid room and 113 institutes have been approved. These figures are not final; every day the government has to examine applications for exemptions and approval.

(3) Another very important result achieved by the Belgian government since the armistice, deals with the medical control of working boys and girls between the ages of thirteen and eighteen, in all factories and workshops of the country.

The coordinated laws on public instruction and on child labor (Act of May 26, 1914) provides for the compulsory medical inspection of all pupils. The same measure will be extended to the older pupils of the second degree schools. After this step has been taken it was obviously impossible to permit the protection of the child's health and the control of his physical development to cease on leaving school, at the threshold of the workshop; just where the harmful influences may be most active and where are gathered the less favored in life. According to this point of view, a royal decree (Royal Decree of June 1, 1920) establishes a sanitary guardianship for the boys and girls at work.

Medical Examinations

According to this decree, boys and girls of sixteen to eighteen must be examined by a doctor at least once a year. Those whose state of health requires it, are examined twice a year, quarterly, or even monthly if needed.

The medical examinations are made by the medical inspector of labor himself, or, under his control, by doc-

tors chosen by the employers. Boys and girls are also authorized to go to another doctor if they choose, but in this case the examination is at their own expense. This occurs but rarely. The examinations are being conducted according to the same method throughout the whole kingdom and the medical inspectors of labor have received specific directions to give special attention to the weak and unhealthy. It can be imagined that an organization of this kind, applied to a country as essentially industrial as is Belgium, is a considerable undertaking. It can also be imagined that, after a few years of existence, it will be liable to restore the level of the working people's health and will later on influence all the future generations. It has already proved excellent, although it is clear that years will pass before it will give its maximum possible output. Here are a few figures concerning its work during the second half of 1922: nine hundred and three industrial firms have organized, at their own cost, means of sanitary protection; 523 doctors, presented by employers have been approved by the Minister of Industry and Labor; 23,481 young people (of which number 8,174 were girls) have been examined; 2.51 per cent of the boys and 3.23 per cent of the girls, every quarter; 0.26 per cent of the boys and 0.16 per cent of the girls, every month.

The medical inspectors of labor send a report to the Minister every six months, on the results accomplished by the sanitary supervisions in their district. One of those reports reads as follows:

All those who are to give their contribution to this work ought to do it with wholeheartedness and spend on it their activity and devotion with the absolute conviction that they are working for the general welfare . . . their most important mission consists in finding out the interesting cases for which prophylactic or curative medical help should be useful, in giving the necessary advice concerning moral or bodily preservation . . . and to watch as a good father, the execution of advised or prescribed measures.

This same report mentions the following facts: 49 cases of diseases of the respiratory tract have necessitated repeated examinations; also one case of circulatory disease, one case

Before Sweeping or Cleaning—Use

Semdac Liquid Gloss

(A SUPERIOR POLISH)

THE period of maximum bacteria circulation in hospital air was found by Tucker to be after sweeping. Neuman found that sweeping multiplied the number of dust-borne germs in the air, by at least 20.

In Boston City Hospital, about midnight, after the wards had been quiet for a few hours, Tucker found in 10 litres of air, bacteria varying from 0 to 13; mould spores from 0 to 4.

During the day, due to varied movements in the wards, the number of bacteria in 10 litres of air ranged to 477 and the number of moulds to 227.

The time to apply Semdac Liquid Gloss is first-off in the morning, while the bacteria-laden dust is still reposing undisturbed, on floor and furniture surfaces.

Semdac displaces, not disperses, dust, thus removing the danger of dust bacteria. Semdac cleans and polishes all finished wood, metal or enameled surfaces, furniture and floors.

Semdac does not gum or stick—for it is scientifically made in the laboratories of the Standard Oil Company (Indiana).

Metatarsalgia and Callouses Caused by Weakened Transverse Arch

This condition is recognized by depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is described by Whitman as Morton's Toe.

These conditions, Doctor, are quickly relieved and permanently corrected by the use of

Dr. Scholl's *Corrective Foot Appliances*

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. Different types to meet all emergencies.

Sold and fitted by leading shoe dealers in

every community who have been instructed in Anatomy of the foot and how to properly apply correctives to the foot and shoe.

Important pamphlet, "*Foot Weakness and Correction for the Physician*," mailed upon request.

THE SCHOLL MFG. CO., 213 West Schiller Street, Chicago

NEW YORK

TORONTO

LONDON

of gastritis, 16 cases of general weakness and one case of albuminuria. Fifteen workmen have been directed to antituberculous dispensaries. In some cases the employer has aided by continuing, for a lighter work or even for a very irregular work, the whole of the salary previously earned.

A great many of the remarks concern injuries which have not needed repeated examinations, and which it has been possible to remedy at once. Among others, we will mention those concerning polypus of the nose, adenoids or hypertrophy of tonsils, hernias and many cases of eye sores, purulent otitis, etc.

(4) Recently created institutions which will contribute strongly to the betterment of conditions of welfare and health of the Belgian workmen are the "Schools of Social Service." The first temporary school of this kind was created shortly after the armistice, under the inspiration of private contributors and with the financial help of the government. The success met by this temporary school and the results already achieved before the war, by similar schools founded by Christian democrats, induced the Belgian government to support these attempts and to give them a permanent character.

Auxiliary Workers

A Royal decree, dated October 15, 1920, provides a Board of the Schools of Social Service, whose mission consists in fixing the curriculum and controlling its practical application. Financial support for the initial cost expenses and the salary of the teachers is provided. The two years course of study results in a certificate of "Social Auxiliary."

The first year provides the general knowledge representing three hundred hours of theory, plus attendance at studying clubs and seminars as well as visits to at least fifty special organizations. The principal subjects taught are: public and administration laws, civil laws in their relation to social service, political and social economy, labor legislation, public institutions, institutions for private education and for social assistance, personal and general hygiene, care of the injured, the sick, and the children, methods of statistics, of record-keeping, etc.

During the second year, the pupils specialize in particular lines. The types of specialization adopted thus far are the following:

Child welfare work.—Staff of the institutions for education and protection of children.

Relief work.—Clerks to the charity bureaus, secretaries to organizations for private aid, social investigators, social visitors.

Institutional management.—Restaurants, canteens, etc.

Industry.—Factory superintendents, inspectors of labor.

Social insurance.—Secretaries of mutual or social insurance organizations, to intelligence-offices and insurance against enforced idleness.

Libraries.—Training of librarians.

Eight schools of this kind are now functioning, and the actual results are encouraging. To mention only the industrial group, the schools training factory superintendents, cannot meet all the applications received from the industrial organization.

Finally, among other activities of the Belgian government, we may mention the effort recently made to ameliorate the medical-pharmaceutical service of the health insurance societies. Since the war an item of more than fourteen million francs is included in the budget for this purpose.

Apart from these endeavors of the state, certain local authorities also took interesting steps. For instance, the war against the ankylostomiasis among the miners was successfully carried on by the Province of Liège, which organized, largely at its own expense, for the study and treatment of this disease. Formerly, the *Ankylostoma duodenale* infected all the mines of this province and seriously affected the health of a great many workers. Today, this nuisance is vanquished and the cure is so thorough, that sometimes it is rather difficult for the laboratories of that region to show some ankylostomes to visitors.

The province of Hainaut has also created, for the detection of the same disease, a dispensary which has proved very useful. It is true that in this mining center, the disease does not present as serious a problem as did the earlier situation at Liège.

Supporting the efforts of the officials, the manufacturers have helped greatly in perfecting the medical machinery put at the disposal of the workmen. These efforts are worth a detailed statement; we will give here some examples chosen in only one region: the establishment of J. Cockreil, Searing; the Charbonnages du Hasard; the group of coal-mines of Montegnée; the factories of Ougrée-Marihay, of the Val St. Lambert, etc. There we find surgical and medical hospitals, homes for old people, orphanages for boys and girls with schools and foundling asylums. All

these have careful medical supervision and are furnished with the most modern accessories.

But if the Belgian state and the manufacturers of this small country have realized considerable progress in prophylaxis the workpeople, on their part, have not remained backward. They also have taken bold initiatives which, we think, are liable to develop more and more. Belgium is the classic soil of "mutual insurance." The workers' societies, whose aim is to provide their members with financial help and medical assistance in case of illness, are so numerous and so common, that one cannot logically conceive the organization of health or invalid insurance without their direct assistance. The bill actually drawn, on this subject, takes this fact into account. It is true, the war, which has destroyed so many things here, seemed to drag after it the decay of a good number of our health insurance societies, but little by little they have risen again; the experience gone through resulted in improving the methods formerly followed and, today, the state of these useful institutions of human solidarity, is far better than in 1914.

The heads of our big Mutual Federations, have, during these last years, taken bold initiatives regarding dispensaries. For instance, the *Fédération des Mutualités Chrétiennes* is in possession of the Sanatorium of Mont-sur-Meuse, one of the most beautiful and best situated in the country. Also, the *Fédération des mutualités et des Unions mutualistes socialistes*, of the province of Liège has created at Seraing, a medical institution and a surgical clinic, often mentioned as a model.

Care of Mental Patients In Pennsylvania

One of the aims of the Bureau of Mental Health of the Pennsylvania Department of Public Welfare is complete state care of mental patients. With this end in view, the licenses have been withdrawn from seven county institutions, in which conditions warranted it, and the patients have been transferred to state hospitals. Another county institution, operating without a license, has been discontinued. Other aims and accomplishments of the Bureau, together with a graphic presentation of its organization, are given by its director Dr. William C. Sandy, in an article entitled "Organization and Scope of a State Bureau of Mental Health," published in the current number of *Mental Hygiene*.

Opium: An International Problem and League of Nations Control

(Continued from Page 32*)

What is a legitimate purpose in the use of these drugs, was the question which precipitated at the Second Assembly discussions that even the moderated language of diplomacy considered "as remarkable for animation as for eloquence," and that for a time seemed to threaten a rift in the harmonious lute. Special conditions still prevailing in India were the immediate grounds for the question. Throughout generations the people of India have in the absence of medical and hospital facilities turned to opium

as a familiar "home remedy," an herbal simple, as cure and as preventive, in case of disease, and a stimulant equivalent of the five o'clock tea of other countries. In the long years of habit, the people of India have learned how to use the drug without injury to themselves and there is little abuse of it. If this use cannot be recognized under the strict terms of "medical and scientific" neither does it deserve the opprobrious designation of "illegitimate." So pleaded the representative from India, supported by the British delegate according to the position taken long ago on this matter and still held by his government.

China withstood the proposed change of wording from "strictly medical and scientific" to "legitimate" until late in the meeting of the sub-committee appointed during the Assembly to consider the point, when yielding seemed preferable to seeming lack of cooperation. The circumstances as a whole, according to M. Van Swinderen's conclusion, justified the change. But Siam withstood the modification even in full assembly. It

is noteworthy that at the first meeting of the Health Committee when this request from the Opium Committee was considered, the same question arose, What is the legitimate use of these drugs? It was summarily settled there as medicinal and only medicinal, and the deliberations of the Health Committee have proceeded upon that basis. And further, according to most recent documents from the League of Nations, India is listed as one of the countries not only as signatory to the International Opium Con-

ed records of amounts manufactured, etc., will later supply data needed.

These two inquiries were, then, authorized by the Second Assembly, with the changed wording in each just mentioned and the understanding that the method would be strictly scientific and the work done through or with the consent of the governments concerned.

As to the first, the investigation by the Health Committee of the League into amounts of medicinal opium, morphin, cocain, etc., required for home consumption of different countries—a

report was presented in January to the Opium Committee from the group of four members representing the Health Committee and two representing the Opium Committee who had as a sub-committee considered the question in hand. The first point in this report has already been anticipated—that "from the health and medical point of view . . . medical use (of these drugs) should be considered the only legitimate use, all non-medical use should be considered an abuse . . . and in the opinion of

Wide World Photo.

vention, but as having adopted the certificate system from January 1, 1923. This is the more interesting because excise was one of the transferred subjects and legislation dealing with it had to originate with the local governments. All of which would tend to confirm rather than confute that "general desire to reduce and restrict the production of opium" even though the interpretation of its legitimate uses may not yet be altogether unanimous. The main object is to have the information regardless of the label it bears at present; and the provisions already mentioned for detail-

doctors the use of opium as a stimulant could not be considered legitimate even in tropical countries." The Rapporteur mentioned the need for acquainting doctors generally with the less harmful drugs which might be used instead of morphin. In order to arrive at reliable statistics of legitimate needs for home consumption, the sub-committee believed that the inquiry should cover a large number of countries, through several years, and should proceed simultaneously upon four distinct lines:

(1) Adding the imports and manufactures of a country and sub-

tracting the exports; (2) direct inquiries made in hospitals, and from chemists, dispensing physicians, dentists, and veterinary surgeons; (3) statistics of disease accumulated by Insurance Funds, General Hospitals, and other sources, compared with figures of narcotics used in the hospitals; and (4) statistics obtained through the use of import and export certificates. The results of all these methods, compared and tested, would give approximately the information sought.

The second inquiry into the legitimate requirements of raw opium in each country, authorized by the Second Assembly was to some extent dependent upon the findings as to amounts of medicinal opium actually required. Pending the report on this point, the Opium Committee recommended that governments be invited to furnish their own estimate of their needs of raw opium. This plan was approved by the Third Assembly, 1922, which bettered the recommendation by urging that such estimates be furnished as promptly as possible, and indicate the method followed in reaching them; also, that a parallel statement indicate the estimated consumption per 100,000 inhabitants. These estimates have been given in sufficient numbers to justify discussion at the May meeting of the committee.

Import Certificates

An important explanation was made of this system during the year by the Secretary General to correct an impression which had deterred some States from accepting this method of control. They thought that the certificate implied a guaranty that no abuse of the drugs imported would be possible. From Sir Eric Drummond's circular letter on the subject two brief paragraphs may be taken:

If a dealer in dangerous drugs in country A desires to import a supply of drugs from country B, he must in the first place, obtain from his own government a certificate that the import of that particular consignment of the drugs is approved by the government and is required for legitimate purposes (or in the case of morphin, heroin, cocaine, or medicinal opium, that it is required solely for medicinal or scientific purposes), and must forward the certificate with or in support of his order to the exporting firm in country B. The government of country B will not issue its license for the export of the consignment of drugs to country A until the certificate has been produced to it by the supplier in country B from whom the drugs have been ordered.

Conversely, if a dealer in dangerous drugs in country A desires to export drugs to country C, the government

of country A will allow the export only on the production of a similar certificate from the government of country C that the particular consignment desired to be exported is required in country C for legitimate purposes (or for medicinal and scientific purposes as the case may be), and that its import is approved by the government of country C.

The system is based on the assumption that each country controls the export of dangerous drugs by a government license. It assures each government adopting its procedure against export from another country without regulation and against evasion of its own regulations. The success of such a system depends, of course, upon its general adoption. At January 1, 1923, thirty States had adopted the certificates, thirteen making the system effective from that date. At the end of April, 1923, the system was in force in twenty countries.

But what will happen if some countries do not adopt this system? The Third Assembly, 1922, inclined to the view that:

Governments which are parties to the International Opium Convention should be asked to agree not to issue licenses for the import of opium from any country which has not yet ratified and put into force the Convention and adopted the system (of import certificates). The Assembly considers this question important and urgent but recognizing the complicated and technical nature of the issues involved, it is of the opinion that the matter should be examined in detail by the Advisory Committee on the Traffic in Opium before any definite action is taken.

To consider this "boycott plan" a special meeting of the Committee was called in January, 1923. Thorough discussion brought out divergent opinions. Underlying the proposal is the purpose of confining the whole trade in dangerous drugs to those countries which are willing to carry out effective control of their imports and exports, and that those states which act independently of this international control will either be induced to cooperate or will cease to find a market for their supplies. Members of the committee who opposed the measure maintained that since India, Turkey, and Persia, were the principal producers of opium and since Turkey and Persia had not ratified the Opium Convention consuming countries would need to import larger quantities from India than heretofore. The result of the measure would therefore be not only to increase the production in India but also, since it was most unlikely that Persia and Turkey would reduce their cultivation, to ex-

tend the very illicit traffic the Committee desired to control. Prices would rise, and smuggling become even more attractive than at present. Perhaps even a group of states not adopting the certificates might arrange to trade among themselves in the drugs concerned. "Restriction of trade" and "coercion" were also urged against the measure.

On the other hand, it was pointed out that any increase of production could be only temporary, since supplies must decrease as control became more effective. Jugo-Slavia and Greece were also producing countries so that a monopoly for India need not be feared. Restriction of free trade is in the very nature of the convention itself and any means of tightening international control would assist in suppressing illicit traffic. At present the efforts of cooperating states were being nullified by the production and trade carried on outside the Convention—in opium, one-third of the world's supplies were controlled, two-thirds, uncontrolled—an impossible situation—and the Assembly's proposal was the only practical one yet made to meet it.

During the debate, word was received that Turkey had intimated a willingness to become a party to the Opium Convention; and also that Persia intended to submit the Convention without reservation to her Parliament. The influence of such courses upon the point at issue was evident, and decision was postponed until the May meeting of the committee.

A bit of comedy in the midst of these serious discussions was the proposal to the Committee by a certain drug firm that this firm relieve the League of Nations of many difficult problems by itself assuming control of the drug trade of the world. Consideration of the proposal was "deferred."

Closely related to the control through certificates, is, of course, the agreement to notify the League of all seizures of dangerous drugs wrongly manifested, with all possible detail of origin and persons shipping the consignments, such additional information to supplement the more formal annual reports, and make possible prompt action in suppressing illicit trade. Just how the plan works—for it is already working—may be illustrated from the case of the registered letter mentioned at the opening of this paper. Quoting from the report of this incident:

The Chinese Foreign Office has reported the smuggling of morphin into China through French and Brit-

Consider the Post-Operative Value of Stanolind Liquid Paraffin

Burrows, in the New York Medical Record, emphasizes the post-operative, intra-abdominal use of medicinal mineral white oil, especially when such oil is of high viscosity.

He says that this oil introduced into the abdominal cavity "prevents recurrence of adhesions, lubricates the intestinal cords, straightens out angulations and kinks, floats the gas-filled loops of gut out of the pelvic cavity, exerts an intra-abdominal pressure upon the viscera, and is followed by a return of normal peristalsis."

Many physicians have hitherto avoided the use of mineral oils of domestic origin. Such physicians will find that Stanolind Liquid Paraffin, (Heavy) is of ideal viscosity and efficient action.

The viscosity of Stanolind Liquid Paraffin is 300-310 Saybolt at 37-7 degrees C (100 degrees F); specific gravity—0.891—0.895 at 15 degrees C (59 degrees F). It is a rich, heavy-bodied, mineral white oil unexcelled for post-operative use; for treatment of all cases of chronic intestinal stasis, and for all other purposes where such an agent is indicated. On account of its slow flowing quality, it produces that steadiness of lubrication which is physiologically desirable.

STANOLIND LIQUID PARAFFIN

(Heavy)

ish postoffices there. The British government later reported that large shipments of morphin had arrived at Amoy concealed in registered mail forwarded through the Chinese Post Office and also through the British and French Postal Agencies, an examination of the covering letters showing that these consignments had been sent out by a firm in Denmark.

The Danish Government having instituted an inquiry at the request of the League, discovered that the firm in question had been exporting morphin and opium at the rate of three hundred kilograms per annum. The Danish government reported that it had expelled the manager of the firm, who is not of Danish birth, from the country and had advised the British government not to grant permits for the export of morphin to this firm in Denmark.

Sources for Contraband

Switzerland is on the trail of persons in that country who had been shipping great quantities of morphin, heroin, and cocaine into Canada. Spain in asking what are the sources in Lyons and in Germany for contraband seized at Barcelona. Greece is watching baggage large and small at Patras at the request of Italy because at Trieste the port police found cocaine in possession of the crew of a British steamer. Narcotics from Germany via Spain via France via St. Pierre Miquelon into Canada, are doubtless the subject of interesting communication between the representatives of these countries on the Opium Committee and their respective home governments.

But drug-takers use drugs not mentioned in the convention. This fact was emphasized by France in 1921, and a list of drugs found in France to be especially liable to abuse was furnished the Opium Committee and sent to all governments for comment. In the committee it was observed that some at least of the drugs on the French list were used as substitutes for morphin and cocaine, and were less injurious. The committee will avoid placing obstacles in the way of obtaining valuable drugs while at the same time carrying out the Assembly's instruction to extend investigations to "all dangerous drugs of whatever origin producing effects similar to those mentioned in the convention."

Several interesting matters in the committee's discussions and activity must be passed over with only mention. Their cooperation with the Transit Committee of the League in securing police measures at Free Ports for detection of smuggling; the form for annual reports accepted by the Assembly; their recommendation that prison sentences be given for

smuggling, since the game is so profitable that fines alone are insufficiently deterrent; their acceptance of the offer made by the League of Red Cross Societies to conduct an educational campaign in the eastern countries regarding the dangers of drug-taking, and their recommendation that all governments consider the advisability of public information on the danger of indulging in drugs; the assistance offered by the International Missionary Council in reports of smuggling; the important ruling by the International Postal Conference in 1920 by which transmission of the drugs mentioned in the Convention is prohibited by letter and permitted in parcels only when of declared value and to countries authorizing such importation. The Far East situation will, it is expected, be discussed again at the May meeting. Japanese traders were apparently the main agents in the contraband trade in North China; and the Japanese Government emphatically declared its intention to stop the illicit traffic, asking the cooperation to this end of all exporting countries.

Holland Steadily Active

The Netherlands government has been steadily active in the duty assigned it of endeavoring to secure ratification of the opium convention by states not yet members of the League of Nations, and of informing non-member nations of the committee's progress. "In this way governments of the Dominican Republic, Ecuador, Germany, Hungary, Mexico, and the United States have been kept informed of the various steps taken during the year," according to the report in 1922. This duty was continued at the request of the third assembly.

At the first of May, 1923, fifty-nine states had signed the International Opium Convention; forty-six had ratified it. Of the signatories, fifty-one were members of the League of Nations. Forty-two ratifications came from League members.

It may be that still the letter rather than the spirit of these laws and regulations of so new an order of things is followed by certain nations. But this possibility cannot obscure the great fact—that the unremitting activity of Secretariat and Committee, all too briefly sketched here, have laid the foundation for that effective international control of dangerous drugs which was one responsibility placed upon the League of Nations. And the response from so many states indicates a growing public opinion which will "carry on."

Relative Values of Aeration and Stirring

Air blown into the aeration chamber of an activated-sludge plant (1) maintains the sludge in suspension, (2) maintains aerobic conditions, and (3) stirs up the mixture allowing fresh liquor to come in contact with the sludge. Bushwell has attempted to determine the minimum air requirements of the microbial growths composing sludge by holding fast at least one of the factors and then balancing the other two.

Experiments were conducted in a 12 gallon tank; the first consisting in a mechanical maintenance of sludge suspension on nidus racks which were dipped in and out of the tank thus producing stirring and aeration. A second set-up was furnished with a filtrous plate and a rotating nidus rack with which good clarification and substantial purification of sewage was obtained in from 3 to 6 hours when using as low as 0.002 cu. ft. of air per gallon. Finally with gentle stirring alone it was found possible to remove from strong domestic sewage 30 to 50 per cent of the difficulty removable colloids. Stirring is apparently much more important than oxygen.

There are six reactions in the activated-sludge process: (1) the air must saturate the liquor immediately beyond the surface of contact—a rapid action, (2) this oxygen must then diffuse to the activated sludge particles—an exceedingly slow process, (3) the dissolved molecular or organic stuff must diffuse to the activated sludge particles—a slow process, (4) the colloidal particles must get to the activated sludge floc—the actual change of position of colloidal particles is practically zero, (5) the organic material and oxygen must be taken up and worked over by the organisms of the sludge floc—probably a comparatively rapid action, and (6) the by-products of the biological growth must diffuse away from the sludge floc; otherwise they will accumulate and poison it.

Of these six steps, all but (1) and (5) are comparatively slow. The only way to speed up the other four steps is by stirring. From the point of view of power output aeration is not the best way to accomplish this. The most efficient process would be one in which the air surface and flocs were held stationary while the liquor is caused to flow past them. (*Eng. News-Record*, May 10, 1923, 90, 19, p. 835.)

The Ideal Castle Combination Sterilizer

THE No. 1512 Castle Sterilizer for instruments, dressings and water is the ideal equipment for clinics and industrial first aid rooms.

It sterilizes everything in a positive and safe manner. It is large enough, and yet compact and trim in appearance. It is a joy to work with and is strongly made for years of service.

Features of the No. 1512 Electric

Neither water nor instruments in sterilizer can boil dry. No fuse pins used. All water in gauge glass sterilized.

CASTLE

Complete line of Physicians', Dental, Hospital and Bacteriological Sterilizers

wholesome, is served at 7:30 a.m., after which rooms are placed in order for the rigid daily inspection to come later. From 8:30 to 11 a.m., is given over to class room periods of one-half hour each.

The class work is devoted to stimulating and developing the latent power of these youths. They are shown that life must include these four essentials: (1) Mental effort, (2) manual skill, (3) spiritual expression, and (4) physical development. In each of the classes some phase of the intimate relation between mind and body, hand and soul is clearly and effectively demonstrated. The boys and girls are given something concrete to think about and later when they go back to their homes in Charleston or Wheeling, in Evenwood or Lewisburg, they carry with them a living knowledge of the fundamental principles of better living. This class work partakes of the nature of vocational guidance, for it produces from the hazy, blurred impressions of the complexities of life, a definite, creative, simple concept.

At 11 a.m. all the groups assemble under direction of the camp leader. Then, the clear mountain air echoes with vibrant song. No anthem was ever sweeter than these children's voices in the cathedral of the great outdoors. After a short discourse, possibly on some religious topic, the bugle sounds the mess call. Group games and recreation are in order for the afternoon. One group may play handball or baseball, while another hikes to Indian Rock or Red Sulphur several miles away. Group games are generally supervised so that the boy who is shy forgets his bashfulness and gets into the game. In the evening, after a welcome and much enjoyed supper, the big camp fire is lighted. Many stunts are presented to enthusiastic audiences, many treasures of the day's work and play are displayed. The camp fire songs rise high to heaven until the bugle call of taps ends the day.

From this brief description of the camp life in West Virginia, it will be seen that the health authorities have a definite problem before them, but more than that, they have an unexampled opportunity to do a great deal of constructive health work. Similar opportunities exist in many other

states. Even the auto tourist camp, which is sometimes looked upon as a form of pest, offers chances for health officials to spread health propaganda. The United States Army has recognized the value of the camp idea and has established a system of Red, White, and Blue Citizens' Military Training Camps. Health is stressed in these camps and one of their primary purposes is to endeavor to correct physical defects.

There is something about the two words, "going camping" which appeals to old and young alike. It arouses visions of pine woods, of glorious days of fishing and tramping, of canoe trips, swimming, and the whole wonderful life of the open air. Perhaps the most important element of all, however, is that intangible influence for better health. For many who go are needy and suppliants for increased vitality. When the embers of the camp fire die down at Jackson's Mill, an impressive stillness reigns about the circle. Standing under the starlight, with hands raised and heads bowed, all chant the Tribal Prayer of the Omahas, "Father, a needy one stands before Thee; I that sing am he."

New York Assembly Act No. 2392

New York state has recently passed "An Act to Amend the Public Health Law, in Relation to State Aid to Counties engaging in Public Health Work." The importance of this action is discussed in the editorial columns of this issue of THE NATION'S HEALTH. The text of the law follows:

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1.—Chapter forty-nine of the laws of nineteen hundred and nine, entitled "An act in relation to public health, constituting chapter forty-five of the consolidated laws," is hereby amended by inserting therein in a new article to follow article two-a, to be article two-b, to read as follows:

Article II-B

STATE AID TO COUNTIES

Section 19.—State aid to counties engaging in public health work.

(19-a) Approval of state commissioner of health.

(19-b) Statement by clerk of board of supervisors; approval; amount of state aid; payment.

(19.) State aid to counties engaging in public health work. Whenever the board of supervisors of a county, exclusive of a county having within its boundaries a city of the first or second class, shall appropriate and expend moneys for the construction, establishment or maintenance by such county of a county, community, or other public hospital, clinic, dispensary or similar institution, or for the purpose of defraying the expenses of such county in any public enterprise or activity for the improvement of the public health, or any public health work undertaken by such county, such county shall receive state aid in the manner and subject to the conditions prescribed in this article. The legislature from time to time shall make appropriation for the purpose of rendering such state aid.

(19-a.) Approval of state commissioner of health. It shall be the duty of the state commissioner of health to formulate standards of construction, equipment, service, administration and work which must be complied with by such counties in order to be entitled to state aid, and no state aid shall be given to any county unless the state commissioner of health, after inspecting and examination by him or his representative, shall make his certificate that such construction, equipment, service, administration or work is necessary to the public health and conforms to the standards so established therefor.

(19-b.) Statement by clerk of board of supervisors; approval; amount of state aid; payment. The clerk of the board of supervisors of each such county shall, on or before the first day of January of each year, transmit to the state comptroller a statement verified by the chairman of board, certified by the clerk, which shall state the amount appropriated and expended during the preceding year by such county for a purpose specified in section nineteen of this article. On or before the first day of March next succeeding, the state commissioner of health shall transmit to the comptroller a certificate stating whether or not the amount specified in each such statement, or any part thereof, was expended by the county for a purpose mentioned in section nineteen of this article, was necessary to the public health and was conformable to the standards established by the commissioner of health. On receiving such approval of the state commissioner of health, the comptroller shall draw his warrant upon the state treasurer for fifty per centum of the amount, as approved by the state commissioner of health, appropriated and expended by each such county, and the treasurer shall pay the amount set forth in such warrant to the county treasurer of the county entitled thereto.

(2.) This act shall take effect immediately.

Safety Museums and State Industries

(Continued from Page 497)

with October 1, a lecture service has been maintained at the museum building. On the first and third Friday evenings of each month, an address on safe practices in industry has been given by the writer. These meetings

equipment is on consignment and may be removed by the owner at will or by the museum management after a reasonable notice. The concrete value of the demonstration is that conformance to standards so visualized be-

Treatment room in Rehabilitation Clinic—Baking and Massage treatments are given in this room.

have been attended by plant engineers, works managers, foremen and others who are entrusted with supervising authority. The attendance has ranged from one hundred to two hundred and fifty persons. A new audience at each of these meetings was assured by getting the various plants in this locality on consecutive evenings to have all of their technical and supervising force visit the museum at an appointed hour.

In addition special arrangements have been made with plant managers who desire to have the museum kept open on a specified evening in the week for the benefit of their employees. At these meetings motion pictures were shown and an address given on Industrial Safety and Accident Prevention.

We feel the museum offers great opportunities to industrial leaders and executives for promoting the safety, health and efficiency of the working people in this state. Approximately one hundred seventy-five thousand dollars worth of equipment has been installed in the building. This

comes a self-imposed task rather than a burden enforced upon industry by the Department. New Jersey is thereby achieving real co-operation.

Injured workers regaining lost function by means of treatment in Rehabilitation Clinic.

Dr. H. E. Kleinschmidt to Toledo

The Public Health Federation of Toledo, needing an executive of broad training and experience to direct its work, has gained its objective by securing the services of Dr. H. E. Kleinschmidt of the American Social Hygiene Association's staff. Dr. Kleinschmidt was granted an indefinite leave of absence and assumed his new duties on May 1.

Dr. Kleinschmidt received his degree as Doctor of Medicine from Washington University in 1909, since which time he has been prominently identified with public-health progress, particularly in the field of graphic education. His work in the preparation of motion pictures, exhibits, literature, and other educational media, has brought him recognition both at home and abroad. During the war he, with many others of the Association's staff, enlisted in government service. Dr. Kleinschmidt was commissioned as an officer in the U. S. Navy, and assigned to promote and develop the social-hygiene program in the Navy, and much of the material which he designed at that time still is basic.

His activities in the social-hygiene field, first as executive secretary of Missouri Social Hygiene Society, and for the past seven years, on the staff of the American Social Hygiene Association, assure the proper emphasis on social hygiene in the program of the Public Health Federation of Toledo.

Dr. Kleinschmidt's friends and associates in the fields of public health and social welfare will wish for him every success in his new affiliation, and a feeling that this success will be achieved accompanies the wish.

New York Studies Maternal Mortality

Five successive issues of *Monthly Statistics Review* of the New York State Department of Health have been devoted to subjects related to maternal mortality. The issue of April, 1923, gives the number of deaths from each puerperal cause according to the International List with rates in proportion to deaths per ten thousand confinements. Figures are shown for 311,872 mothers who gave birth to 304,463 live children and 10,886 stillborn children; of these mothers 1,996 died from causes connected with childbirth. The percentage of error that occurs in average statistics of this kind makes the New York contribution unusually important. The matter is a large and serious problem.

4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

GROUND GRIPPER

WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

Analysis of Reduction in Death Rate

(Continued from Page 536)

TABLE I.—THE TREND OF MORTALITY FROM CERTAIN GROUPS OF CAUSES. U. S. EXPANDING REGISTRATION AREA: 1900-1920.

Causes	1900	Death rate per 100,000 in—			
		1905	1910	1915	1920
All causes ²	1,755.0	1,602.0	1,495.8	1,355.1	1,306.0
Group I	422.8	359.8	326.0	241.7	193.9
Group II	757.4	772.1	741.0	735.6	679.1
Group III	574.5	470.2	429.0	372.6	433.0

expanding Registration Area) and summed for each of the summary rubrics. The final data are presented in Table I and are illustrated in Figure 1.

In the figure we have plotted the specific death rates for each of the three groups of causes of death against a logarithmic instead of the usual arithmetic scale of ordinates. The virtue of this procedure is that the slope of each curve to the horizontal represents the *rate* of change in the death rate and the rate of change in each curve is directly comparable with the slope (i. e. rate of change) of the other curves regardless of the size of the death rate. On such a scale a straight line represents a curve whose *rate of change* is constant.

From an examination of Table I and of Figure 1 it is clear that although the death rate from "all causes" has been declining, the rate of change in the different groups has been notably different. The decline in the death rate has been most uniform and most marked in Group I (the causes of death against which the public health program has been specifically directed); the decline has been least notable in group II (causes of death which have received little or no attention in the public health program of the first two decades of this century); and has been more irregular, though more marked in Group III than the decline in Group II and less marked than the decline in Group I.

TABLE II.—DECLINE IN MORTALITY FROM CERTAIN GROUPS OF CAUSES. U. S. EXPANDING REGISTRATION AREA: 1900-1920.

Causes	Per cent decline in death rate			
	1900-1910	1910-1920	1900-1920	
All causes ³ ...	14.8	12.7	25.6	
Group I	22.9	40.5	54.1	
Group II	2.2	8.4	10.3	
Group III	25.3	0.1	24.6	

In Table 2 we have presented some derivatives from Table 1.

It appears that the decline in the death rate from "all causes" amounted to 14.8 per cent in the ten-year period 1900 to 1910. In Group I, this decline was 22.9 per cent, in Group III 25.3 per cent and only 2.2 per cent in Group II. In the decade 1910-1920, the corresponding percentage declines were: "all causes," 12.7; Group I, 40.5; Group II, 8.4; and Group III, 0.1. For the whole period, 1900-1920, the decline in Group III was approximately the same (24.6 per cent) as for "all causes" (25.6 per cent), and the decline for Group I was more than twice as great (54.1 per cent) and for Group II less than half as great (10.3 per cent) as for "all causes."

We are well aware of the shortcomings and inaccuracies inherent in mortality data which, in an ultimate analysis, are based upon the statement of "cause of death" upon death certificates. Nevertheless it appears to us from the tabulations presented in this note that the decline in the death rate during the twenty years 1900-1920, when analyzed according to the method used here, is wholly reassuring to the public health worker and indicates that his efforts have not been in vain. Our conclusion, it is recognized, is wholly *post hoc ergo propter hoc*. And though there has been a general decline in mortality from all causes of death it is exceedingly unlikely that at least a very substantial portion of the greater decline in Group I can be attributed to any factors which are not part of the public health program. It appears to us to be outside the domain of probability that those causes of death which have been the declared objects of the public health program for the control of morbidity and mortality should happen to be the ones which would show

consistently greater declines than the average. Indeed, it appears to us that the differential analysis of mortality which we have attempted here indicates clearly that twenty years of public health activity has yielded clear-cut and substantial reductions in mortality.

Refugees' Diet Contains Ration of Yeast

To rear children with nutritional aid from yeast is the aim of an interesting experiment being tried in Near East Relief orphanages at Athens, says the *New York Times*. A thousand subnormal children suffering from hardships in the exodus from Anatolia, will be selected for supplementary feeding with vitamins, in order to demonstrate how far these so-called accessory food products can combat and repair the results of prolonged malnutrition.

Recognition of the permanent benefit to Greece resulting from the American Red Cross sanitation program among the million refugees from Asia Minor and Thrace who are now in Greece has been shown by the Revolutionary Committee now controlling the country. Colonel N. Plastiras, chief of the committee, has issued an order directing all prefects, Military Governors and police directors of the nation to give full cooperation in carrying out American Red Cross measures, and calling upon every Greek citizen to do the same as a matter of duty.

Dayton Provides Care for Its Babies

Despite the fact that the weather ran from "showers" to "blizzard" on four out of the six days of the annual baby conference conducted by the Division of Health and Visiting Nurses Association of Dayton, Ohio, from May 6 to 12, 967 babies were examined. The greatest number examined on any one day was 360. The rapidly declining death rate which was lowered to 67.5 in 1922 was reflected in the improved general appearance of the babies. This is becoming more evident with each recurrence of the annual baby week states the *Bulletin* of the Division of Health. "During this conference as well as in the weekly clinics it is unusual to see puny, scrawny babies. A few years ago such sights were common in the yearly conference and were the rule rather than the exception in the clinics."

Treating Abscesses in Antrum and Sinus Regions

Dr. Horace B. Coblentz, of Washington, D. C. reported in the *American Journal of Electrotherapeutics and Radiology*, the case of an abscess in both the frontal sinus and antrum region. Application of Radiant Light and Heat produced a hyperemia and the return of blood and lymph circulation. After opening and draining the abscesses, daily applications of the light rapidly completed the recovery of a very serious inflammation.

The Radiant Light and Heat were applied with

Safety Pays for Itself

(Continued from Page 441)

ducted which was attended by approximately twelve hundred superintendents, foremen, and gang leaders from their plant and other plants in the district. The management were so pleased with the success of their venture that they asked that a course be planned for the workmen. The committee which had conducted the foreman's course after careful deliberation and planning decided to conduct not a lecture course, but a system of playlets or sketches demonstrating dangerous practices which result in injury. Eight of these sketches were shown, each by a different department. The result of these meetings was remarkable. For the five years previous to the meetings the plant had had an average of five hundred seventy-eight lost time cases per year. The year after the meetings the plant had only thirty-five lost time accidents or about one-sixteenth of the average for the previous five years. The hospital bill for the year preceeding the meeting was nine thousand dollars. For the year succeeding the meetings it was six thousand dollars.

There is an intangible benefit secured by an industry engaging in safety work that cannot be shown in percentages of accident reduction or in the saving of money. When foremen and workmen come together in safety meetings, large or small, they go back to their work broader and better men because they have met together and discussed problems common to all. American industry tends more and more to specialization which means monotony and narrowness of outlook. By interesting the foremen and workmen in safety it lifts the individual out of the rut and broadens his vision. Another intangible benefit of safety in the association of superintendents, foremen, and workmen in safety committee meetings in the plants. I have seen the foremen and men from various departments in safety committee meetings in groups of from five to fifty. The discussion has been frank and free. All the cards were laid on the table. If a recommendation proposed by a workman were not feasible, he was told so and the reason why was explained. Not only is safety discussed, but also sanitation, welfare, and kindred topics. These meetings cannot be surpassed for the promotion of good fellowship and cordial relations between superintendents, foremen and men.

Maximum production, which means dividends to the stockholders and a full pay envelope to the workmen cannot be accomplished with buildings and equipment where no regard is paid to safety, sanitation, and pleasant working conditions, but with due regard for these, production will reach its greatest efficiency.

The Use of Morbidity Studies Among Miners

Mine operators and managers for a number of years have known that the maintenance of health among the workers has an appreciable financial value, says Chief Surgeon R. R. Sayers of the Bureau of Mines, in a report of the Subcommittee on Prevention of Illness of the American Institute of Mining and Metallurgical Engineers, presented at the New York Meeting, February 19-22, 1923 (Serial No. 2453, U. S. Bureau of Mines).

Mortality statistics are probably the most easily available indices as to the hazards of industry. However, both field and laboratory studies are limited in value in that such studies usually have been made over a comparatively short period. While we have some information as to their immediate effect, we do not know to what extent extreme heat, humidity, the presence of dust or other health hazards are the cause of disability.

While the data obtained from morbidity statistics out of material aid in the prevention of sickness, they only show the last illness and give no information as to previous health conditions of the individuals. Furthermore, no information is given as to the exact nature of their work other than a very general statement as to occupation. It is this limitation of the knowledge supplied by death certificates that makes sickness records so necessary to lessen or eliminate the health hazards of an industry.

One lead smelter in the United States has a full-time medical and safety organization which makes physical examinations of all applicants for employment and at intervals thereafter. Sickness records are kept of all illness. This company decreased the yearly incidence of lead poisoning from eighty-seven cases to thirty-five cases in four years. However, they had not compiled and an-

alyzed their records during the period, but on doing so found that the decrease in the number of cases was chiefly among those occurring about the blast furnace. At this point the number of cases was decreased from forty-seven occurring during a year to five cases during a like period. The analysis of the records further showed that there had been but little or no decrease in the number of cases occurring about the preheaters and charge floor—twenty-four cases as compared with twenty-two cases per year at the end of the period. A physical examination of each of the employees in the above departments was made at once by the plant physician and over 60 per cent of the total number were found to be leaded. The conditions in the three departments were investigated and practical means taken to eliminate the hazard.

Usually there is no valid reason why companies having a full-time plant or mine physician can not record what is happening to the health of the population in which they are interested. Records of sickness, of course, are kept in practically all establishments which provide medical service for employees, but usually they cover only those cases that are treated in the plant dispensary or company hospital. Obviously, a record of all the cases occurring in the population under study is necessary for determining the relative frequency and severity of disease according to occupation. It is also necessary to have available the same set of facts for the persons not sick as for the persons sick so that comparisons can be made in terms of rates per 100 or 1,000 persons in any given period. A card 5x8 (inches), used by the U. S. Public Health Service and several large industrial plants, is suggested as being suitable. Reprint 573, Public Health Reports, gives an explanation of the terms used on this card.

Anti-Hookworm Campaign in Honduras

The anti-hookworm campaign in Honduras, begun in June, 1922, has included 20,031 examinations and given 12,245 treatments for intestinal parasites. Branch clinics have been established in several provinces, carried on with full cooperation between the local and national governments.

Cleveland reports that its garbage reduction plant has been self-sustaining for all but two years and shows a profit from its by-products.

Home Nursing Care of Infantile Paralysis Cripples

Stories From the Day's Work of the Committee for the Aftercare and Study of Infantile Paralysis of the Visiting Nurse Association of Chicago

By EDNA L. FOLEY, SUPERINTENDENT, VISITING NURSE ASSOCIATION, CHICAGO.

EVERYONE knows something about infantile paralysis—the epidemic poliomyelitis since the epidemic of 1916, when there were 27,000 cases reported in the United States alone; but, until recently, little has been said about the value of home-nursing care after the acute stages have passed; indeed, far too little emphasis has been put upon muscle training and the prevention of deformities by means of the correct posture of the affected parts—joints, back, arms, legs, et cetera.

Of the thousand or more patients who have passed through the hands of the visiting nurse since the big epidemic, a few illustrations will suffice to show what this new treatment can accomplish. Just six years ago the author saw a five-year-old victim of the epidemic of 1916, crowded into a baby-carriage far too small for her. Leg, arm, back, and abdominal muscles had been left so weakened that she could not stand, or even feed

herself. The spine showed a marked functional curvature and the legs obliged to assume in the carriage.

Field of Muscle Training Widens

NOT EVERY nurse can render adequate after-care for the paralytic cripple. Stiff preparatory training, directed sympathy, and the utmost patience are required; but the selected groups who have submitted themselves to the essential discipline have found this special field a laboratory out of which has evolved a new technic of the widest application. The mastery of dysfunction through voluntary effort to perform the motions and exercises worked out in accordance to the needs of the part affected has made a place for muscle training in any scheme of corrective gymnastics for sick and convalescent patients that has received too little emphasis in public health nursing.

There was some power in the left hand and forearm for, when the busy mother had time to pinch a pencil between the right thumb and forefinger and to place the left hand on the right wrist, Katie could painfully draw scrawls on a bit of cardboard until the pencil tumbled over.

Katie was the youngest of seven. Her father was a bad provider and her mother was a laundress. Their basement reeked with all the odors that usually accompany the squalor implied by the above conditions. So seriously paralyzed a child would have seemed an institutional patient but both Katie and her mother had seen enough of hospitals during the five dreary weeks of quarantine. Even the plaster shells applied to keep the legs straight, had been stripped off as soon as the child reached home, in order that she might be more easily tucked

were quite helpless and deformed, both as a result of the paralysis and as the child reached home, in order that she might be more easily tucked

into the old baby-carriage that never was far from her mother's side.

After a thorough dispensary examination, the treatment advised here was rest, correct position in bed (preferably on a Bradford frame), plaster shells for the legs, a platform splint for the right arm, a daily salt tub-bath followed by a very gentle massage and later, ever-so-carefully graded muscle exercises for legs, arms, back and abdomen, plus a weekly visit to the orthopedic clinic. The muscle examinations showed a trace of muscle power in nearly all of the affected muscle groups but the deformities caused by the action of the unparalyzed, opposing groups made any sort of success through care in such a home, most unlikely. The mother was plainly not interested; the father, openly antagonistic. In fact, the family has moved many times in order to escape this unwelcome supervision. It has kept the truant officer busy, for today Katie goes to school. To be sure, she wears a removable plaster corset and uses crutches, for the abdominal muscles are very weak, but her leg braces have been discarded, both forearms are normal, her left shoulder muscles are returning gradually and only the right deltoid is giving a lot of trouble.

This result has cost more than four hundred home-treatment calls, varying in length from fifteen minutes to an hour and a half; about seventy visits to the clinic, at first in a taxicab but now by streetcar; many hours of plasterwork brace-fittings, and examinations on the part of a keenly interested surgeon; bribes of dolls in pink dresses; loans of Bradford frames and a wheel chair; gifts of several plaster jackets and removable spicas, of two braces and several pairs of shoes. A lot of time and money, perhaps, to put on a stupid little child of ignorant, illiterate parents, but the investment was not in vain, for Katie has inherited some of her father's pugnacity and

when the clinic, the nurse and the school get through with her, she will be a self-supporting, vocationally-educated young woman, not a helpless liability, spending weary years in the alms house or equally dull ones selling matches on street corners. And to doctor, nurse and teacher alike, Katie and her affairs have been a liberal education, for in this one home we have seen illustrated all angles of the poliomyelitis problem: the need for better early hospital care, for more prompt follow-up and home supervision, for adequate clinic and

et cetera—and the careful exercises and close supervision have brought about this marked physical improvement without any surgical interference. Katie demonstrates what can be done in spite of a variety of conflicting circumstances. If we could have commanded adequate convalescent home facilities and intelligent, sympathetic help from either or both of her parents, we might have been able to accomplish a great deal more for her.

Although it has been estimated that 80 per cent of poliomyelitis patients

are less than five years old, recorded ages have ranged from eight months to nearly fifty years. One patient in particular was a young school teacher only twenty-six years old, who was apparently hopelessly deformed and paralyzed from the flexed thighs, which drew up her knees, to the badly twisted feet. Stricken in the height of her usefulness, she came to us from a relative's home, where for two years she had been a helpless dependent, tied to her bed or a chair—a hideous existence for a proud-spirited young woman whose only misfortune was her poverty. Through summer residents who had heard of our work, she was brought to Chicago, given a free bed in a good hospital, an operation was performed by a member of the orthopedic staff and six weeks later she was fitted with leg braces and given crutches. Of course she was still per-

These three children were apparently hopelessly crippled when their case was undertaken in 1917. To the girl now able to hold the dumbbell, such effort was then impossible. The one at the left is learning to balance, and the one in the middle has so far advanced that it is hoped she can one day walk without crutches. All are now in school.

home-nursing service, and for a special school that will adapt its system to the needs of the handicapped child. For Katie has been a medical, orthopedic, nursing, social and economic problem all these years and through her, we have learned what not to do for many scores of similar cases. Two things Katie has never been: a relief or a surgical problem. In spite of its poverty, the family has never asked any aid other than that made necessary by the child's condition—casts, braces, dispensary care,

perfectly helpless, but straight. Then began months of nurse-training. She was given daily exercises to coax back any latent action and to strengthen and re-educate the felt powers in the affected muscle-groups. Gradually she was taught balances and the use of crutches. She was under treatment nearly nine months; then a sister came down for a week to learn the most obvious exercises and the patient returned to her home village. To make a long story short, a recent letter said that she was doing all of the

housework, even the floor-scrubbing, in a three-room apartment, tutoring two hours and doing eight hours of office work daily, had made a new organdie dress and gone to a garden-party—not a bad showing for treatment covering less than three years. This patient is wholly self-supporting; she was both physically and economically dependent when first referred to us. She will always need braces and crutches, walking will never be easy; but she is independent and on her own.

These two stories describe different but difficult patients and I could tell of many more like them. At present the Committee for the Aftercare and Study of Infantile Paralysis of the Visiting Nurse Association of Chicago has nearly eight hundred handicapped patients under its supervision. At least six hundred of these are receiving fairly regular home or school treatments at the hands of fourteen especially equipped visiting nurses. Our experience has taught us that this sort of work does best under the supervision of a special committee, the personnel of which is made up of well known, interested physicians and orthopedic surgeons and lay people equally active in the proper care and education of crippled patients.

In organizing, the committee selected three clinics that were fairly convenient, geographically, for most of our patients. Since then we have added two others. All of our free cases are sent to the nearest one of these five clinics and nearly all of our free home work is done for clinic patients. In only a few instances are we carrying patients who are not under the direct supervision of orthopedists and about 80 per cent of our children are clinic patients. Every patient receiving home treatment is under medical supervision. A surgeon from each clinic, two physicians, who, in 1916, represented the only hospitals admitting acute poliomyelitis cases, and Dr. Frank Billings, long a member of the advisory committee of the Visiting Nurse Association, constituted our first medical subcommittee. The other members of the original committee were selected

from the board of directors of the Association. At first a special fund was raised to pay for equipment, transportation, and the salaries and expenses of the nurses, and instructor. Later on we were given a Ford sedan. Then the expenses of the nursing staff, including salaries, were taken from the annual budget of the Association and now our special fund is needed only for equipment, braces, crutches, etc., and the chauffeur's salary.

Before our first survey of the 1916 cases was completed, we began to look for ways and means of giving the home treatment. We tried to put the children into the general district work but the nurses knew very little about the prevention of deformities, correct position, muscle examinations and

all of the more important muscles. The weak muscles are hindered by the strength of their opposing groups, therefore all muscles must be studied, not merely the affected ones.

Too much emphasis cannot be laid upon this need of a very thorough and stiff training in anatomy for any workers who are going to give the actual muscle training treatments in infantile aftercare work. A superficial knowledge helps just as knowledge of correct and faulty posture helps but if the home treatments are going to be given regularly and faithfully, so that weakened muscles may be spared over exertion and coaxed back to a semblance of their former strength, an accurate knowledge of the entire muscle system must be in the possession of the workers making the examination and planning the exercises. Mothers and helpers may be taught to give the treatments under supervision, but the exercises must be worked out by experts.

A bed-ridden or wheel-chair cripple is something of a burden to himself and his friends. If he can be taught to sit down, to walk on a level, and to go up and down stairs, he is pretty nearly independent; consequently, from the first we have tried to stress the kind of treatment that would make these three things possible.

From the beginning we found that infantile

paralysis, although an acute infection, affects nearly every patient differently. The exquisite tenderness and soreness that make the acute stages of the disease so difficult to handle, will persist in some cases for weeks and nothing except warm tubs can be attempted until this soreness is past. In other cases the soreness wears off much more quickly and treatment can be instituted earlier. It is generally admitted now that patients in the acute stages should be under the observation of orthopedic surgeons from the onset of the disease in order that deformities, especially of ankles, knees, hips, and shoulders, may be prevented. The position in which the patient lies—(Continued on Page 567)

One such child as this constitutes one of the most complicated problems we have in medical, orthopedic, nursing, social and economic service. The care involved is a liberal education for all concerned in her re-education.

muscle exercises. Most nurses think that they learn anatomy while in the hospital. They merely learn to pass examinations; they actually know very little about muscles and nerves and bones and tendons. In our first year, we were fortunate in securing an instructor who was not only a graduate of the New Haven Normal School of Gymnastics but who also had had training and practice with Dr. Robert Lovett of Boston. This allowed us to organize good class-work. The nurses from the first were given a very great deal of anatomy for it is impossible to make a careful muscle examination and to work out the needed exercises for any patient unless one has an accurate knowledge of the origin and insertion and action of

Medical Observations Made on the Zuñi Indians

Being a Resumé of Medical Observations Made During the Hendricks-Hodge Expedition to Hawikuh

By HENRY CRAIG FLEMING, M.D., NEW YORK CITY.

PURSUANT to the desire of the director and of one of the trustees of the Museum of the American Indian, Heye Foundation, that medical observations be made on the Zuñi Indians, the writer was enabled to conduct the investigation whose results are incorporated in this paper, during the archeological researches by the Hendricks-Hodge expedition of the Museum at the ruins of Hawikuh, in August, 1921.

The Zuñi reservation is situated in western central New Mexico, extending to within about eight miles of the eastern boundary of Arizona, and covers an area of 288,040 acres. The average altitude of the valleys is approximately sixty-five hundred feet above sea level. Most of the surface consists of flat, rolling, and rugged country covered generally with sagebrush, cacti, and other lesser growths, together with some juniper and piñon trees. An occasional oasis, spring, or shallow stream, together with a capacious reservoir fed by the waters of the Zuñi river, makes a limited agriculture possible. Frequent rains occur during a portion of the day in the summer season, but the moisture is so soon dissipated by the dry sand and soil, and the hot sun, that both man and beast encounter obstacles to their existence during a large part of the year.

The population of the reservation was 1,863 according to an official statement by the Commission of Indian Affairs in 1921, of whom there were 1,063 adults, 800 minors; 1,040 males, and 823 females.

The Zuñi Indians are distinctly pueblo dwellers, living in stone and adobe houses of one or more stories, of which most contain two or three

communicating rooms, with few small windows situated high above the earthen floor, usually kept tightly closed and thus affording little or no ventilation. Entrance is by way of a

and the trading post or general merchandise store, and there reside the reservation physician, a missionary, and several white settlers connected with the local day school and with the trading post.

The Indian agent, who administers all Federal business relative to the inhabitants, lives at Black-rock, about four miles east of Zuñi, and here are situated also the Government school, and the irrigation reservoir above referred to.

As the masses of the Indians are entirely ignorant of even the simplest laws of hygiene, it is obvious that sanitary conditions are most primitive. Human excrement is frequently deposited in the open, close to the houses in which swarms of flies "blow" the jerked mutton which is commonly hung upon strings or poles to dry for winter use.

Superstition and ignorance cost the population many lives annually through pernicious practice of the medicine men and women. And it is unfortunately true that but little or no medical intelligence and efficiency are evident.

The plan of study for making these observations was that of procuring Indians at random, of both

sexes and of various ages, for general physical examination, including Wassermann analyses and blood smears and counts, inspection of the pueblo, general living conditions and customs, and such history taking, by the aid of an interpreter, as might lend constructive support.

At the beginning the writer was advised that difficulty would be encountered in procuring subjects for study owing to the Indians' shyness, superstition, and even resentment of the proposed study. Such, however, did not develop to be the case, for not

Here Age Does Not Mean Uselessness

THE careful blood pressure readings made revealed much lower averages than exist among white peoples. Many men approximating seventy years of age, in extremely active pursuits, registered systolic pressures between 110 and 125, and diastolic pressures between 60 and 75.

Fischer, whose long-lived group exhibited the common characteristic of low blood pressure readings, would find in the constitutionally low pressures of the Zuñi men an explanation of their longevity.

He would, however, willingly concede that zest for life in the aged men of these pueblos is due in part to the fact that with them age does not mean an easy life of self-indulgence or involuntary retirement from competition with their kind. The joy of the race is theirs until the journey is done.

rather narrow doorway, while ascent to the roofs, to which the Indians frequently resort, as well as to the upper stories, is possible by external ladders.

The principal pueblo or village upon the reservation is Zuñi, or Shinakwin, situated on the Zuñi river at an altitude of 6,282 feet. Three less important ones are Nutria, Pescado, and Ojo Caliente. These smaller pueblos are occupied chiefly during the farming season and are in close proximity to large springs which irrigate the surrounding valleys. In Zuñi itself are situated the postoffice

only did we not experience a single exception to our wishes, but on the contrary many Indians, entirely unsolicited, volunteered for such studies as we desired to make.

From the standpoint of stature and skeletal development nothing unusual was observed. The Zuñi men range in height from five feet six to five feet ten, with perhaps the majority between five seven and five nine. Most of the women are from two to five inches shorter. The muscles are not large, but are extremely resilient and often very powerful, thus affording great agility and marvelous endurance. The bodies of the younger men are unusually well framed but slender, with readily visible ribs and relatively prominent joints. The feet and legs are well developed, although the muscles are not nearly so large as one would expect to find in a people who run so much as the Zuñis do. There is a striking contrast between them and the jirrickisha men of Japan and China.

It is a common sight to see one or more of these Indians while going from one pueblo to another, a distance of fifteen or more miles, run the entire distance without stopping to rest. And a favorite pastime is their national game of *ti-kawa-we*, or the race of the kicked stick. This is played by two competing teams usually of four or more runners each. Two cylindrical sticks are cut, one for each team. They are about five inches in length by about half an inch or less in diameter, and are differentiated by distinguishing red paint marks.

The race is run upon the open prairie over a prescribed course which usually extends from fifteen to twenty miles. Both teams start at the same line, at a given signal, and run the entire distance without abatement, kicking the sticks as they go, but at no time being permitted to touch them with their hands. Even in the event of its falling into a cactus clump or into a prairie-dog hole, the stick must be recovered and further propelled by the foot only, under penalty of disqualification should it be dislodged in any other way. So imbued is the Zuñi with the idea that the stick helps him, instead of himself being the sole motive power of the stick, that he will frankly state that without the

stick he could not possibly cover so great a distance in so short a period. It is, therefore, a common practice when traveling considerable distances on foot for these men to kick a stick before them.

Examination of eight of these runners immediately after the finish of a stick race, at which time they were bathed in profuse perspiration, revealed comparatively no evidence of fatigue, no respiratory distress, and no heart rate above 106 beats per minute.

The Zuñi men range in height from five feet six to five feet ten. The bodies of the younger men are unusually well framed, but slender. The muscles are not large, but extremely resilient. The Indian shown is balancing on the foot the painted stick used in the national game of *ti-kawa-we*.

Blood pressure determinations by the acoustic method, the diastolic being read at the fifth phase or point at which the pulse sounds disappeared, of approximately one hundred fifty adults, revealed much lower averages than are found among white people. Of sixty-five cases ranging in age from 50 to 70 years, of which sixteen were women, the systolic pressure ranged from 120 to 130, with diastolic pressure from 58 to 85. The average range of pressure in seventy-four cases between the ages of 25 and 50, was systolic 110 to 125, and diastolic 60 to 75, with no appreciable elevation of either pressure in the older cases of this series. In no instance of the cases examined did a systolic pres-

sure exceed 145 or a diastolic exceed 85, unless there were perfectly definite subjective distress and objective evidence of cardiovascular or renal disturbance.

The writer was surprised to find many men of approximately seventy years of age leading lives of extreme physical activity, performing feats requiring great endurance, and registering systolic blood pressure between 110 and 125 and diastolic pressure between 60 and 75. In one instance, that of Gaialito said to be 75 years of age, an old warrior, the systolic pressure was 110 and the diastolic 80. This man revealed a definite *arcus senilis*; as was true of many others, a slight impurity of the first sound at the cardiac apex, and suffered marked impairment of vision from trachoma, but otherwise was presumably well and not only performed hard manual labor daily, such as digging, but also entered competitive games, such as tug-of-war, with considerable success against younger competitors.

In one instance, a man said to be fifty-five years of age, apparently in normal health, the systolic blood pressure was 100, diastolic 75. In another case, a man of fifty, apparently well, registered systolic 105, diastolic 60. A few cases revealed systolic pressures between 150 and 220, with corresponding elevation of the diastolic pressure, but in each of these cases there was evidence of disease to account for the hypertension.

Altitude unquestionably exerts some influence upon blood pressure, and the study of this has been approached in two ways:

- (1) By a study of the pressure of people living at various altitudes.
- (2) By the use of the pneumatic chamber to change the atmospheric pressure.

The approximate relation of atmospheric pressure to altitude is illustrated in the following table from Casmus:

Atmospheric pressure Mm. Hg.	Altitude Meters	Altitude Feet
760	0	0
750	1,148	3,760
660	2,370	7,760
460	4,022	13,200
350	5,945	19,470
260	8,600	28,180
200	11,000	36,040

It has been demonstrated by Schneider and Hedblom⁴ that in pass-

ing from 1,700 to 1,600 feet falls of relative pressure of from three to seven mm. Hg. occurred without changes in the average diastolic. In ascending from six thousand to 14,109 feet, they found an average fall of both systolic and diastolic pressures of seven mm. Hg. and an average rise of pulse rate of 26 beats per minute.

Clough² detected no significant variation in the average blood pressure of individuals living at an altitude of 5,000 feet and those at sea level. Studies by Gardiner and Hoagland³ corroborate in large measure the findings of Clough. They studied individuals living for a year at an altitude of six thousand feet and found their relative pressures only slightly lower than those observed in persons of the same age and sea level. Smith⁴ believes that an altitude of 6,230 feet does not produce any consistent alteration of blood pressure in either normal or tuberculous individuals.

It seems logical to conclude from numerous studies made that although ascension tends to lower blood pressure, the degree of lowering is insignificant in the average individual, although the exception is occasionally witnessed in hypotensive individuals. When appreciable lowering of pressure does occur it is more pronounced in the systolic pressure.

The writer finds no record of studies of blood pressure having been made upon Indians living at various altitudes or of Indians passing from one altitude to another, but he finds no reason for attributing the remarkably low pressure of the Zuñi to the altitude at which they live.

It is well known that hypotension may occur following hemorrhage, in acute infection and in chronic conditions of malnutrition or cachexia, in amyloid disease and in cyclic and or-

chostatic albuminuria, in anaphylaxis, nicotism, alcoholism, in endocrine abnormalities and in other pathological states. Facilities for excluding certain possible contributing factors to

Gaialite, an old warrior, said to be more than seventy-five years of age, performs hard manual labor daily and has considerable success in competitive games—such as tug-of-war—against younger men.

the low pressure of the Zuñis were not available on the reservation where these studies were made, but the writer believes their hypotension to be constitutional. If this conclusion be correct, it is interesting to note the paradox of the Indians' great powers of endurance and stamina as contrasted with the average white man's deficit of these qualities if he be the subject of low blood pressure.

Inaccuracy regarding the ages of the cases was inevitable because these Indians do not keep record of the date of birth, and it therefore becomes a matter of conjecture, usually deduced by determining how large a boy or a girl the subject was at the time some well known event occurred in their lives.

One hundred twenty-five differential blood counts were made upon apparently normal men and women of the aforesaid series without detection of abnormality of the white or red cells or abnormal variation of their numerical relationship.

Seventy-nine specimens of blood for Wassermann analyses were procured from men, women, and children, carefully packed on ice and delivered within forty-eight hours at the laboratory of the Albuquerque Sanatorium. In this series the following results were recorded: Five positive; sixty-seven negative; and seven anticomplementary.

Contrary to the prevailing lay belief that the Indian in general is destined to die of tuberculosis, the writer found evidence of this disease in but seven of about two hundred and fifty cases examined. These examinations, however, consisted of physical methods only, for laboratory and x-ray facilities were not available. In the seven cases presenting definite signs of lung disease, four were third stage cases and confined by their disease. For the greater part the men, women, and children, although in many instances thin, even emaciated, from lack of proper food, presented well developed resonant chests with normal respiratory sounds.

Evidence of syphilis too, was very uncommon, as illustrated by lack of physical evidence and negative Wassermann findings.

The one most serious disease prevailing amongst the Zuñis is trachoma. This disease is rampant, almost universally prevalent among them, and seriously imperils their vision. The writer saw many cases in which large, hard masses had formed upon the conjunctiva by coalescence of the primarily discrete granules, thus creating ulceration, opacity, and in several instances complete destruction of the cornea with resulting blindness. The—(Continued on Page 550)

The race of the kicked stick, covering a course of fifteen or more miles, is played by two competing teams of four or more runners each. Needless to say, foot troubles do not exist among them.

Vitamin B as a Factor in Nutrition*

Whether Its Merit Lies in Its Food Value or in Its Stimulus to Food Utilization, Vitamin B Is a Dietary Essential

BY GEORGE R. COWGILL, SHEFFIELD LABORATORY OF PHYSIOLOGICAL CHEMISTRY, YALE UNIVERSITY, NEW HAVEN, CONN.

VITAMIN B was the original dietary essential to which the term vitamin was applied.

As has been the case with many interesting discoveries in physiology, interest in the group of phenomena suggested by the word vitamin really began with observations made of a pathological condition; in this case the observations were made on human beings suffering from the disease beriberi, which is of widespread occurrence among the peoples of the Far East whose most common staple food is polished rice. This interesting disease is characterized by a paralysis involving chiefly the limbs together with certain alimentary and cardiac symptoms.

In 1890, Eijkman,¹ a Dutch physician on the Island of Java, reported observations made on his barn yard fowls; symptoms in these birds similar to those characteristics of human beriberi were described by him, together with experiments which he made to determine the cause of the malady. Later it was suggested that this disease was caused by the absence of some necessary substance from the food; this suggestion, however, did not meet with ready acceptance. There were some who believed that beriberi was caused by pathogenic organisms present in moldy rice. The usual tests by which such organisms are identified and shown to bear causal relationship to disease were made and negative results always obtained in the case of beriberi. It was suggested by other students of this problem that a toxin was present in the rice but experiments designed to test this hypothesis always yielded negative results. Some investigators

made serological and immunological studies of beriberi and likewise failed to secure any indications of the presence of antibodies or similar biological products in the body fluids of patients suffering from this disease. The complete failure to secure positive findings supporting any of the various seemingly more acceptable hypothesis advanced to explain the origin

sciences of bacteriology and immunology were making remarkable discoveries regarding the causation of disease. It is not to be wondered at, therefore, that the acceptance by medical authorities of the deficiency disease idea has occurred only comparatively recently.

The crucial test of the vitamin hypothesis has rested on these facts:

- (1) that the pathological condition in question only occurs when the individual—man or animal—has subsisted for a considerable period on a deficient diet;
- (2) that the abnormal condition is cured by the administration of a sufficient amount of some source of the appropriate vitamin, and
- (3) that when the organism is fed the deficient diet together with a daily small but adequate amount of a source of the vitamin, the pathological condition does not develop.

Such facts as these involving vitamin B have been obtained from feeding experiments performed on man and animals. In the light of what is now known regarding vitamin B, a satisfactory explanation can readily be given for the fact that beriberi, which had been such a scourge in the Japanese navy, was caused to disappear almost entirely by changing the ration offered to the sailors.

It is quite obvious that advance in the study of vitamin B can only be slow if students of this problem are to wait for cases of beriberi to appear before observations and definite experiments can be made. As a matter of fact the greatest progress along this line has been made by investigators working in a different field of study.

Ever since it appeared that the various foodstuffs—namely, protein, carbohydrate, and fat—seem to subserve different functions in the living organism, physiologists have had as

Food Interest and Food Relationships

TO THE average person vitamin is a word to conjure with, so impressed is he with the dire pictures of deficiency disease described as due to the addition or subtraction of seemingly trifling amounts of certain food substances.

It is well that the pathological conditions entailed by defective dietaries are specific, for along with biologic tests of food values comes the knowledge that a satisfactory balance between health and disease is in such cases so definitely possible of control.

The importance of the whole subject of nutrition makes us particularly expectant in awaiting the "future research prizes" of the food chemist. It also gives interest to the contemplation of the habits of those peoples whose dietary régime has given them longevity and almost complete freedom from nutritional disorders.

of beriberi only served to emphasize the fact that this disease, so far as its cause was concerned, belonged to a category quite different from those among which diseases had hitherto been classified: a new class was therefore established, that of "deficiency diseases."

The idea that a pathological condition may be induced by the continued absence of something from the diet was none quite difficult for students of medicine to grasp, being propounded as it was during a period when the

*The first of a series; articles to follow will deal with vitamin A and vitamin C.

1. An excellent account of the work of Eijkman and other students of beriberi is given in E. P. Vedder's book, "Beriberi," by William Wood & Co., 1913.

a tempting problem for research, that consisting in feeding animals successfully over long periods on purely artificial mixtures of these substances together with a suitable supply of inorganic materials such as are needed by the animal body. Such experiments as these of course really require for their success a knowledge of the very fundamentals of the science of nutrition. As would be expected, the earlier experiments of this sort were failures. Perhaps the most significant suggestion as to the cause of failure was received from the work of Professor F. G. Hopkins² of Cambridge University in England, who showed that a diet that was inadequate for rats could be made complete by the daily addition of an amount of milk too small to permit of its beneficial effect being attributed to the protein, carbohydrate, or fat contained therein. These experiments suggested that milk contains some hitherto unrecognized substance—or substances—which must be present in the diet in order to maintain proper nutrition.

This work of Hopkins was soon followed by that of a great many other investigators, all of whom secured experimental evidence to support the hypothesis that in addition to the known essentials for nutrition such as protein for example, there are others which are required in only relatively small amounts; these newly discovered substances have been variously labeled, perhaps the more common designations being "accessory dietary essentials," "accessory food substances," and "vitamins."

Problems Converge

It is at this point that we find the study of beriberi and the investigations in the science of nutrition converging. Funk, who had accepted the idea that beriberi is a deficiency disease and had used the beriberi-like condition occurring in pigeons fed on polished rice as a basis of study, made many attempts to isolate from rice polishings and yeast the curative principle that was so potent against this disease. Although he did not achieve this completely, Funk came very close to it and secured a material that was extremely effective in curing pigeons of their beriberi-like condition even when used in almost infinitesimal amounts. Because he believed his material to be of *vital* importance to living organisms, and be-

cause this product appeared to belong to the group of substances designated by the organic chemist as amines, Funk proposed to call this important compound a *vital-amine* or *vitamine*.³

Since Funk's introduction of this word, students of nutrition have discovered the existence of other substances, which are necessary in very small amounts, for adequate nutrition; the description of these sister vitamin materials does not properly belong to this article. In order to distinguish these dietary essentials from one another, it has been proposed that the word *vitamin* be used to designate the group and that each of the members of the group be given, for want of a better designation, a letter.⁴ Thus we have at the present time, vitamin A, vitamin B, and vitamin C. As other substances essential to nutrition and possessing the properties characterizing the vitamin group are discovered, they may readily be classified by this system. Using this nomenclature, the antiberiberi vitamin has been given the title of vitamin B, one which it will doubtless hold until some organic chemist determines its chemical nature, whereupon a new name based upon and suggesting the exact chemical structure of the molecule of the substance will be conferred upon it. Discoveries of the exact chemical nature of each of these vitamins are among the research prizes of the future.

In recent years considerable vitamin B research has revolved around topics of interest in answering the question as to what people should eat in order to insure an intake of this important dietary essential.⁵ It has been shown that this vitamin is quite widely distributed among the common foods of mankind; that some foods are richer than others in their content of this important substance. For example, egg yolk, tomato juice, and dried yeast contain relatively large amounts whereas ordinary white bread has but little, and such a substance as beef extract from which bouillon for convalescents is frequently made, contains none of it whatever. The importance of such facts particularly to the doctor, nurse, and dietitian, hardly needs discussion. It is to research along these lines, and particularly to the discovery that dried yeast is unusually rich in its content

of vitamin B together with extensive advertisement of this fact, that we owe the recent prominence of vitamins in drug store windows, on billboard posters, and in other places.

It has been shown that, while animals at all ages require vitamin B, the growing organism is particularly sensitive to a lack of this substance. For this reason, the young rat has been selected by many investigators as the experimental animal for vitamin B studies. It should be stated that not all students in this field are agreed that the substance which cures beriberi in animals is identical with that which a young organism requires in order to grow normally. Research to date has not definitely settled this question.

The discovery of the importance of vitamin B in the maintenance of physiological well being has very naturally raised questions as to its function in the body. Why is it necessary? Such a question has to do more properly with the physiology of vitamin B, its mode of action in the organism.

Consideration of the fact that a starving animal does not develop symptoms characteristic of vitamin B deficiency, whereas one which persists in eating the deficient diet does eventually suffer, has led to the suggestion that the vitamin plays some part in the normal transformations which the better-known foodstuffs, namely carbohydrate, protein and fat, undergo from the time they are digested to the point where they leave the body as various excretory products. Some studies have been made testing the idea that the proper handling of carbohydrate by the body depends in some measure upon vitamin B, but no conclusive experiments along this line have been reported. A very similar notion has been suggested by different investigators: the vitamin may aid in some way the chemical changes of the energy-yielding foodstuffs, and, if this be true, the body's requirement for vitamin B may be greater if much exercise is indulged in. However, a very recently published study of the effect of exercise on the young rat's need for vitamin B reports that the animal's requirement for this substance is uninfluenced by muscular activity.⁶

The close relationship which vitamin B bears to the desire to eat is a recent observation of much interest; perhaps—(Continued on Page 561)

2. F. G. Hopkins, *Jour. Physiol.* xlv, 425 (1912). The particular experiments reported in this paper were undertaken to put upon a more quantitative basis results which were obtained as far back as 1906-07. The results of these earlier experiments were summarized in lectures delivered at Guys Hospital in June, 1909.

3. This word was introduced by Funk in 1911. A complete account of Funk's work and ideas concerning beriberi is given in his book, "Die Vitamine," published in 1914 by J. F. Bergmann at Wiesbaden. A recent English translation of this book is also available.

5. The literature concerning this work is very extensive; perhaps the most complete recent review of it of interest to the general reader is given in *The Vitamins*, by H. C. Sherman and S. L. Smith, 1922. The Chemical Catalogue Company, New York.

The Cripple's Place in Society Through the Ages

Social Horror of Deformity Productive of a Bitter Introspection Which Is the Cripple's Chief Handicap

BY ALEXANDER HORWITZ, A.M., M.D., F.A.C.S., ASSISTANT PROFESSOR, ORTHOPEDIC SURGERY, ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, ST. LOUIS, MO.

LIFE is recognized by all as an economic struggle for existence. It is a trite saying that those who are unfit must succumb in this encounter, whether the struggle be mental or physical, but how, and by whom is the term unfit determined? Physical or numerical force directed toward an unfortunate is not always a just criterion. One physically weak or deformed very often proves a potent factor in society. By reason of this weakness his relation to society is frequently of a peculiar nature, influenced by a mentality working introspectively. Physical weakness or inferiority in an individual creates a peculiar state of mind, a mind on the defensive and desiring to obtain by other means that which a poor physique renders impossible. The unfortunate seems always imbued with the idea that he has been unfairly treated in the distribution of bodily favors, that society is opposed to him, regarding him as a useless being with no place in the economic structure. He becomes touchy, spiteful, vindictive and even malignant. This state of mind is reflected in all of his dealings with his fellows, and, in a man of power, with dire results: Witness, Alexander Pope, Alexander H. Stevens, and others.

In this paper the term cripple will be used to embrace deformities both congenital and acquired, malformations of limb and stature. It will thus be used in its original sense of "creeping." We will not enter into a discussion of congenital deformities, but the word "cripple" in the sense just given, leads us to contemplate Darwin's theory in this connection.

A cripple, that is, one differing in bodily appearance from the accepted

normal, a normal established by us who are the majority, is one who at some stage in its intrantrine development has met with some hindrance which checked further development in all or in part of the organism. It is thus a retrogression from the human

and the higher the species the more rapid relatively is the transit through the lower stages.

This retrogression in the human was not always acceptable to his more fortunate brothers who indeed regarded him as a true retrograde. He

was looked upon as a monster who had invaded in an unaccountable way a field foreign to him. *Homo sapiens primitivus*, always at war with his brute neighbors, regarded this strange product in his midst as something foreign and hateful, a product possibly of some diabolic influence. It resembled some fanciful creature the gravid mother had observed. At all events it bode ill for the tribe or family to which it came and the gods must be propitiated. What more natural or agreeable sacrifice than the monster itself?

The human mind in the early stages of civilization could not conceive of the imperfect, attributing it when present to some malignant influence. Our own word "dwarf" presents an interesting history. This word is derived from the Sanskrit "dhvaras," an evil spirit, suggesting that it was either the evil one incarnate or a product of

malign influence. The uncanny appearance of a being in miniature or crippled was repulsive and in itself suggestive of something malignant. This view was held throughout the development of human civilization, Chinese, Indian, European, and American. Religions of high and low morality, ancient and modern alike abhorred this unfortunate and heaped curses upon him. If the Chinese ordered his destruction, Christian Teutons did likewise. If the nomad tribes of Europe destroyed him for expediency, the highly civilized Spar-

The Cripple No Longer On the Defensive

THE ultimate goal of scientific endeavor is the elimination or control of all inherent defect. We enumerate our cripples now and special hospitals throughout the country provide every facility for early correction.

Best of all, the understanding attitude offers every possible opportunity for physical and cultural development while removing the causes of maiming accidents, for we are learning not to close the mental circuits of the physically handicapped.

Under such a system the personality defects due to distrust, a sense of inferiority or mental resistance are prevented and the erstwhile horrid cripple is free to become a social asset.

to some prehuman type. According to Hall (*Adolescence* Vol. 1), the individual in a general way, in the process of cell generation, repeats the history of its species passing slowly from the protozoan to the mitozoan stage, so that we have all traversed in our own bodies ameboid, helminthoid, piscian, amphibian, anthropoid, ethmoid, and we know not how many intercalary stages of ascent. The early stages of transition are telescoped into each other almost indistinguishably, so that phylogenetically the embryo lives a thousand years in a day

tans did so for apparently the same cause, though their method of reasoning may have been different.

Fear of the Deformed

The dislike or fear of the deformed may be attributed to one of four causes or conditions: dislike of the imperfect as among the Hebrews; economic reasons—the knowledge that he will be a burden upon the community; contribute nothing to the state; or that he will make a poor soldier, as among the Spartans; the idea that an imperfect body must harbor an imperfect mind as among the Romans; and the fear that the evil spirit must be concerned in the production of the monstrosity, as among the Europeans of the middle ages.

The imperfect in nature was always abhorrent to the human mind. The human figure, regarded as the acme of perfection in nature when normal, appealed to all of a man's senses; when abnormal the repulsion was equally as strong. This idea was highly developed among the Hebrews. They did not permit a cripple or deformed Levite or priest to officiate in the temple. No element of superstition entered into this. They regarded Jehovah as the supreme King possessed of some human attributes. These attributes existed to a vastly less degree, however, than among the Greeks. Since the Hebrew himself abhorred the imperfect and would not send a deformed or crippled ambassador to a mortal king for fear of offending his sensibilities, why send one of this type to the King of Kings? The laws of Moses here offer a striking contrast to those of Lycurgus. A cripple, priest or layman, was not to be destroyed. "Thou shalt not put a stone in the path of the blind" illustrates the relation of society to the physically unfortunate. The crippled priests were not permitted to officiate in the temple, but were given their share of the bread and the holy things. Among the infirmities preventing them from entering priesthood are (Book 3-21:18-19): lameness, too great length of one limb, broken leg or arm, crooked back, or dwarfed stature.

That a friendly spirit and sympathy always existed toward the unfortunate among the Hebrews is illustrated by a discussion in the Talmud (Sabath 6—fol. 66) whether a cripple should be permitted the use of his crutch on the Sabbath. This ordinarily was a double violation of the law. The pious Jew was not permitted to carry anything on the Sabbath, nor to touch objects the use of

which was forbidden. In the case of the cripple both of these objections were waived and he was granted permission to use his supports.

According to Daniel (1:4) persons with any physical blemish were not admitted to the court of the Babylonians, indicating the same abhorrence for the imperfect, but not carried to the point of destruction. The Babylonians were a military race comparable to the Spartans among whom a different condition prevailed. The entire fabric of Spartan society depended upon its soldiery, who must of necessity be perfect. We are told that every child at birth was brought before the assembled elders of its tribe who decided whether it was worthy to live and whether it was likely to become a useful member of the community. Those sickly or deformed were destroyed by exposure.

Among the Romans "*mens sana in corpora sana*" was a slogan. The right to destroy his children was vested in every Roman *pater familias*, and if he wished to abort the life of a cripple he was not called to judgment. Society as such did not demand this sacrifice.

The belief that the evil spirit was concerned in the production of the deformed and that he must be destroyed was prevalent as late as the days of Luther. At that time a belief was current that the devil helped maidens to the joys of motherhood against their wishes, and that these joys were of a singular nature in that the relation with the devil must result in the most horrid monstrosities. It was also believed that the devil gave these monstrosities to other decent people. Luther could not free himself from these beliefs (Hugo Magnus: *Die Aberglaube in der Medezin* s. 70). To the contrary he once heard that in Dessau such an unfortunate birth had occurred, and in all earnestness he advised that this product of diabolical love be thrown in the Mulde. According to medical judgment this monster was a rachitic child twelve years old.

Doctrine of Sin

The deformed was regarded either as the seat of evil, the devil incarnate, or the product of evil, in any case the result of sin. This doctrine of sin in this connection is variously applied:

(a) *Sin committed by the individual as responsible for crippling conditions:* This has been admitted in ages long before the etiology of these conditions was understood. In Luke V-21 paralysis is evidently regarded as a visitation of God's wrath for sin

committed. Jesus commands the paralytic to arise because his sins were forgiven. This view is not far removed from our present day conception of the etiology of certain forms of paralysis, following *tuberculous dorsalis* and syphilis of the brain. Do we not still ascribe these to sin? With the full knowledge of the causation in mind we do not shun or attempt to destroy an individual so afflicted, but rather offer sympathy and an attempt at amelioration. Naturally we do not adhere to the theory that absolution from the sin causing that disease will act as a curative agent, but we do attempt something along the same lines—to restore the sufferer to his original healthy physical condition before the sin was committed.

(b) *Sin committed by an ancestor near or remote:* The sins of the father shall be visited upon the children even unto the fourth generation. This theory we also admit, as in the ravages of syphilis. Although among the Hebrews this was the prevailing doctrine, still the persons so afflicted were not regarded as outcasts or as conceived in sin. They could not, however, abandon the idea that a supervision from above regulated these things. This is attested in the case of Jacob, whose crippled condition they attempted to ascribe to a supernatural origin. In all ages, even among comparatively recent writers (see Byron's "The Deformed Transformed"), all deformities were regarded as congenital. The Hebrews seem to offer an exception to this. Jacob's lameness was evidently a congenital dislocation of the hip. They assigned a traumatic cause but of supernatural origin. A fracture or dislocation among all peoples however primitive called for an immediate attempt at reduction. In the case of Jacob no such attempt is recorded. He remained a cripple and to this day his descendants are forbidden to eat the sciatic nerve of any animal, since this was injured in the struggle of Jacob with the angel of God.

The sin of the immediate ancestor may vary. Transmission of a disease or a mere sin of transgression of a command suffices. The medieval idea that the devil was concerned in the pregnancy of an unmarried woman illustrates this. We have not entirely rid ourselves of this idea, although a monster need not necessarily be the result.

Early in the history of the human race the idea must have prevailed that the evil spirit was resident in the human monster or cripple. We have pointed before to the Sanskrit word "dhvaras,"—(Continued on Page 565)

A Scheme for Classification of Delinquency in Children*

Pressing Issues Concerning the Problems of Treatment and Prevention

By FRANKLIN G. EBAUGH, M.D., DIRECTOR, NEURO-PSYCHIATRIC DEPARTMENT, PHILADELPHIA GENERAL HOSPITAL, PHILADELPHIA, PA.

THE problem of juvenile delinquency constitutes one of the most pressing issues that confront physicians, court authorities, parents, teachers, and social workers today. The extent of this growing problem necessitates a well balanced and constructed scheme for its study, especially directed with the viewpoint of understanding the facts that enter into the normal behavior response of the delinquent and formulating preventive measures.

In the approach to this problem from the clinical-psychiatric point of view, we must consider: (1) What are the personality assets of the individual that enter into his delinquency? Can we modify these so as to give better adjustment to the environment? (2) What is the situation that confronts the individual and how can we change this situation or environment so as to secure better adjustment?

To sum up, therefore, in studies of maladjustment, we must evaluate the emotional assets of the offender, the intellectual resources, the type of habit formation and instinctive development. In the study of the situation, we have the specific environment data to start with, such as—the character of home life, friction in the home, behavior of other members of the family which may influence the individual and condition later delinquent traits. It is well known that the experiences of the child may later dominate and pre-determine his behavior reactions.

Working from these points of view in a study of several hundred delinquents in a state home for boys,

we found the following classification of delinquency to be a helpful and workable one since it represents a summary of many factors found to be of causal relation to the behavior disorders present. This classification can be grouped into five heads, viz.—

bad companions; incongruity between home conditions and ability.

Habit and instinctive maladjustments also play a rôle in this group. Mental conflict, as a result of unusual early experiences with repression; lack of habit training; mal-

development of inner life; sex ruminations; day-dreaming tendencies; lack of correct sex knowledge must also be considered in the diagnosis and treatment of personality defects.

In the organic group, delinquency is found to be associated with definite organic disease such as syphilis, traumatic conditions, post-encephalitic behavior disorders, and tension states.

In the mental deficiency group delinquency is associated with definite reduction of mental capacity and ability, especially as demonstrated by the imbecile and moron groups.

Cases of infantilism, especially noted in pituitary dysfunction and disorders of the pluriglandular types, fall into the endocrine group.

The psychotic group includes adolescents who may present many features of actual psychoses, such as schizophrenic reactions, manic-depressive states, paranoid states, and constitutional psychopathic inferiority.

After tabulating the above tentative classification, one is confronted with the actual treatment of the boy or girl. We feel several abstracts may illustrate the types of individuals encountered, as well as show the value of the general dictum:—Always make a careful study of the exact situation in which the first delinquent trait was exhibited and determine the driving forces at work that resulted

First Classify; Then Prevent

PERSONALITY defects are of all degrees from those that manifest themselves in mild but excessive emotion under ordinary conditions to states of menacing pathologic maladjustment.

All degrees of delinquency are exhibitions of personality defect due to intrinsic or extrinsic causes. They may be classified as detected, but remedy lies in concerted work among parents, teachers, social workers, court officials, psychiatrists, and physicians.

Well equipped clinics, easy of access, for early diagnosis and grouping of cases for intelligent handling through out-patient clinics or observation wards in psychopathic hospitals are urgent needs of an adequate system of treatment and prevention.

personality defects group, organic group, mental deficiency group, endocrine group and psychotic group.

Personality Defects Group

This group includes neurotic children, emotionally unstable, over-active and under-active types and those suffering from bad environmental influences such as may be illustrated by the following: lack of parental correction, friction between parents or between brothers and sisters; poor hygienic arrangements; influence of

*Presented at the Medical and Psychopathological Symposium on Delinquency and Social Maladjustments, held at the Municipal Court of Philadelphia, February 23, 1923.

in offense against authority and property.

Our fundamental ideas of treatment are derived from observation and a study of the individual as a whole. In this study, always avoid deceit, avoid misstatements, treat with absolute fairness and squareness.

The following cases illustrate the role of the situation in delinquent careers and the degree of final adjustment:

Case 1, E. C.—A girl, age 14, was referred to the clinic with statements that she had been very indifferent in school, had been failing the last two months. She had been very impulsive and had been subject to frequent outbursts of temper. Recently she ran away from home to New York, from which place she was promptly returned by the Travelers' Aid Society.

Examination revealed an attractive girl of normal physical make-up. Her intelligence quotient is 115. The patient was very apathetic and disinterested during the interview. She was very reluctant to talk about her condition. Later, however, she admitted that she had a great upset last November. At this time, a boy friend, of whom she was very fond, insulted her and attempted to abuse her. Since this time, she has been preoccupied and frequently day-dreamed concerning this experience and had been unable to concentrate her attention to school work. Following this upset she began playing truant and, after a quarrel with her mother, who refused to allow her to go out any more, she got up at 2 a. m. and ran away to New York.

During the interview, it was explained to her how her behavior difficulties could be associated with her emotional upset and conflict. She admitted there was a relationship between the two and readily grasped these facts.

Since she has good insight into the nature of her difficulties and has followed our advice regarding an increase of her interests, she has not played truant and has improved in her school attitude. Her parents and teachers mark a general change in her behavior along all lines.

Case 2, S. S.—A boy, age 13 years. Committed larceny on numerous occasions; was unmanageable in school and was sent home because no one could discipline him. He was a failure in 4th-A. His delinquency began seven years previously, when the family moved to Philadelphia.

The patient was very sullen and had a defiant attitude during the examination. He felt he was always

blamed for everything that went wrong at home. He admitted sleeping in the cellar all night to keep from having his older brother "bawl him out." He also stated that he had planned to run away.

The patient's father is an invalid and his older brother assumed full responsibility for him and gives him daily prolonged lectures on "how boys go wrong," etc. The patient pays no attention to these. He states all members of the family are constantly wrangling with him. The usual punishment is to make him walk home from school with a younger brother who is a year ahead of him in school. The patient refuses to do this.

There has not been any improvement. The relatives could not be re-educated or see the advisability of less discipline and more encouragement and interest in the boy and his problems. They refuse to consider a change in environment.

Case 3, E. L.—The patient, age 15, frequently ran away from home and was very destructive. She had periods of temper outburst, was extremely religious. There was a history of possible sex offenses. She had no respect for authority of any source. She enumerated many physical complaints.

The patient revealed a normal physical examination. Her intelligence quotient is 76. She states she ran away because—"They had no use for me." "I would have to fight with her all the time," referring to her stepmother. Patient was extremely upset when older sister changed her religion and felt she should make up for her sister's mistake. She admitted sex delinquencies and preoccupations regarding them.

There was a change in environment with improvement after removal to Catholic Home. Ten months later, she again became restless and admitted occasional stealing and untruthfulness. This necessitated her return home, where she now is getting along better with her stepmother, who feels she appreciates home more than ever before. She continues over-religious.

Case 4, M. G.—The patient, age 8, was incorrigible, cursed and fought her mother. She lay on the floor, screamed and kicked. She beat her head against the wall. She behaved better with strangers, but had no respect for her mother and at times was destructive.

The patient's intelligence quotient is 110. She created a general disturbance in the clinic, yelled and jumped around, cursing and kicking every one near her. She was therefore admitted to the Psychopathic Ward.

A study of the situation was very striking in that it revealed that patient was taught to swear by her grandmother, and also never to pay any attention to her mother. She never had any supervision or discipline or habit training of any type at home.

Patient showed normal behavior response and adjustment to discipline of ward after a few days. She has begun school and is showing no behavior difficulties. There was a change of environment by means of Catholic Children's Bureau, which resulted in normal adjustment.

Organic Group

Case 6, V. L.—A boy, age 7 years. Patient had a prolonged attack of encephalitis January, 1921, with marked mental sequelae consisting of a hyperkinetic state with emotional outbreaks and impulsive behavior. He stole, had screaming spells, was quarrelsome and antagonistic. He had attempted to kill his brothers and sisters with a knife. He frequently kissed girls on the streets and showed marked sexual precocity. He was committed to the Philadelphia General Hospital by the Municipal Court for observation. The patient gradually improved under a fixed ward and occupational routine.

Mental Deficiency Group

Case 6.—The patient, a boy, age 11 years, was referred to the clinic on account of truancy. "He steals anything he can get," "pinches every child in school and has been unable to make any school progress." He is said to be doing 2nd-A work and has been in this class for three years.

Examination reveals that the boy shows a marked reduction in mental capacity and ability. Stanford and Healy A and B tests reveal a mental age of seven years and his intelligent quotient is 59. All reactions, both mental and physical, were slow. He showed poor distribution of attention. His performance tests were done at the six year level. Physically, he was undernourished and under-developed.

The boy has been unable to progress in school and his continued delinquency made it necessary to send him to a House of Detention. Since we consider this child trainable, we have recommended an appropriate institution where his education can proceed as outlined by his abilities and disabilities.

Endocrine Group

Case 7.—The patient was referred by the school with statements that recently—(Continued on Page 562)

The Method of Sewage Disposal in the City of Brockton

Plain Sedimentation and Trickling Filters are Used in Conjunction with a Sand Filtration Plant

BY HAROLD S. CROCKER, CITY ENGINEER, BROCKTON, MASS.

THE City of Brockton at the present time has a population of about seventy thousand. It is an inland city, situated at the upper end of the watershed of the Taunton river. The main drainage stream is very small, and therefore allows no opportunity for the disposal of sewage by dilution from its discharge therein.

The sewerage system was constructed in 1893 and 1894, and put into operation in November of the latter year. The system is a separate one, all surface drainage and ground water being excluded. The main intercepting sewers which collect all the sewage terminate at the southern end of the city in a covered storage reservoir, which has a capacity of about five hundred thousand gallons. The sewage leaves the reservoir proper, passes through a bar screen with three-quarter-inch openings, and enters the pump well, where it is picked up by the pumps and lifted through the force main to the disposal works about three miles away, in the extreme southwestern corner of the city.

The original method of sewage disposal adopted by the city was intermittent sand filtration. The area selected for the plant was admirably adapted for the purpose; there was no population in the immediate neighborhood, the nearest house being about 750 feet distant, and there being only about twenty-five dwellings within half a mile. The geological formation of this area was a coarse sand, with about two feet of subsoil and loam above. On this area twenty-three beds, each being about

an acre in size, were constructed.

The building of these sand beds was very simple, as the entire top soil was removed and piled to form the banks between the individual beds, and the sand surface was then graded to form a level plane.

Underdrains were constructed under each of the beds to carry away the effluent to the Coweaset River, another small tributary of the Taunton. This river, so-called, has a dry weather flow smaller than the quantity of purified sewage therein discharged.

The disposal works have been in

seen that the Brockton sewage is very highly concentrated, with a high color due to manufacturing wastes. It was found that a dose of about eighty thousand gallons of sewage applied every other day to each bed would give a highly purified effluent that could be discharged into the stream.

The original method of operation was to pump once or twice during the day time, depending upon how fast the reservoir filled. (In the earlier days of the system the reservoir would easily store the night flow.) At the end of the day, when the reservoir was pumped down to within

about a foot or a foot and a half of the bottom the agitator was started. The agitators was a series of pipes with numerous openings, laid on the floor of the reservoir, through which sewage was introduced under pressure from the pumps. The sludge that had settled was thereby forced into suspension, and pumping was continued until all the sludge was

charge of a chemist since they were put in operation, and the dosing of the beds has been done in accordance with the results he has determined for the most successful working of the plant. From the time that a public water supply was constructed practically all services have been metered, with the result that the per capita water consumption is very low, being at present only forty-four gallons per inhabitant per day.

The industry of the city is the manufacture of shoes and allied products. As no water other than from the measured water supply and a very small amount of infiltration enters the sewers, it may readily be

stored in the force main, where it remained until the following morning. When pumping started the next day the sludge was pumped to one of four beds reserved for the purpose. This sludge after drying was raked up, sold to farmers, or buried in the low land at the plant.

With the increased number of connections, due to the extensions of the system and the increase in population, new area was needed. The best part of the natural deposit of sand at the disposal works lies to the west, across the city limits in the town of Easton. Legislative authority was asked to acquire that land, without success. Seven new beds were con-

structed in 1904 and seven more in 1908, making the total area at that time thirty-seven acres of sand. With the 1908 construction all available land suited for sand beds had been utilized. In 1911 a revolving screen of very fine mesh—forty holes to the inch—was installed at the reservoir to remove all the solids from the sewage, so that the four beds reserved for sludge could be used to treat the screened sewage. The same year a half-acre of trickling filter was constructed as an experiment. This filter was built of crushed stone varying in size from one and one-half inch to three inches and had an average depth of six and one-half feet. The

concrete floor sloped from one side to the other and had a total pitch of one foot. Six-inch split tile pipe was laid on the floor one foot on centers to collect the effluent, and discharged into the main collecting conduit which emptied into a secondary settling basin that had a detention period of six hours, wherein the sludge was settled. The effluent from this tank was piped to the last installment of seven sand beds for final treatment. The sewage was applied to the

stone bed through nozzles that sprayed the sewage for one and one-half minutes and then stopped for a like period. The entire area received the same amount of sewage. This was accomplished by building a small concrete tank of sufficient elevation to furnish the necessary pressure for the nozzles to spray properly, and the intermittent spraying was effected by the use of a butterfly valve operated by a cam that was driven by an electric motor.

During this period of enlargement, beginning in 1904, the increased size of the plant did not keep pace with the increase in sewage flow, so that actual purification results were slowly on the decrease.

Not being satisfied with the trickling filter even when being dosed at the rate

of about 1,250,000 gallons per acre per day—a low rate compared with most plants—experiments were carried on with the Activated Sludge Process. This method of disposal gave a very wonderful sparkling effluent, but a very large amount of sludge was developed, the disposal of which probably would have caused some difficulty during cold weather. A further experiment was tried by discontinuing the use of the rotary screen and using the receiving reservoir as a partial settling basin. It was not constructed for that purpose, but considerable settling action occurred, enough, in fact, to warrant the permanent discontinuance of the revolving screen.

fine screen, purification at all parts of the plant increased, and the labor cost of maintenance decreased.

Further experiments were carried on during the war time with trickling filters of different depths. The size of stone was varied in these filters, and layers of different sizes were also tried until the most satisfactory combination was discovered.

As a result of the considerable amount of experimentation on plants of various kinds and sizes, some idea of what might be expected of various methods of disposal as far as the local sewage was concerned had been obtained. It might be well to state here that each individual sewage is a

problem unto itself, and one must prove for himself what method is best adapted to local conditions and not adopt a system because it was successful elsewhere.

The adoption of a preliminary treatment for the sewage was a simple matter. A short experiment with an Imhoff tank had not shown results that it was hoped might be obtained. As before mentioned, fine screening had not been given a first class chance to show results; and, in fact, it

One acre of the Brockton plant in operation with the nozzles spraying, and in the foreground a bed under construction, showing the flushing gallery and the method of laying the split tile pipe for collecting the effluent. The dosing mechanism is in the valve house at the right.

It seems only fair to say that the screen never had a real chance for success, as it was located above the top of the reservoir and the raw sewage had to be raised to its level by a small centrifugal pump. This resulted in a double churning action, once in the pump and again on the screen. The result was that the heavy part of the sewage was divided into such small particles that the voids between the several particles of sand at the top of the filters became clogged and the beds required constant plowing and harrowing to keep them in operation if the sewage was to be satisfactorily purified. This colloidal matter passed through the entire trickling filter process with the result, of course, that purification was quite low. With the elimination of the

did not give any satisfaction as a preliminary process. Furthermore, the screen being at the pumping station produced two places where sludge was accumulated, and it would have been much better to confine all refuse to one place. Such good results had been obtained by plain sedimentation with a structure not designed for that purpose, that it was decided to adopt the method and construct a tank of proper design, provided other things were equal. A screen located at the disposal works would have to be housed and the building heated. This would have meant an outlay of at least \$15,000, as compared with nearly fifty thousand dollars that the sedimentation tank cost. The maintenance costs, however, were very much different;—(Continued on Page 582)

Oregon Leads in Rehabilitation of Industrially Injured

Tragedy Is Transformed Into Opportunity and Development of Newly Found Capacity Keeps the Worker's Future in His Own Hands

BY FRANK H. SHEPHERD, FORMERLY DIRECTOR, VOCATIONAL REHABILITATION, CORVALLIS, OREGON.

THE state of Oregon has had, and we think still holds, the leading place in the United States in the work of returning victims of industrial accidents to remunerative employment. We were and are blessed with a law, brief in content, but far reaching in its administration. The purpose of the law, as clearly stated, is to return victims of industrial accidents to the industries. The money for this work is derived from a certain sum set aside from the workmen's compensation fund and replenished as used by a definite per cent of the fund paid in by the employers and employees to the workmen's compensation fund. The administration of this fund is left entirely to the State Industrial Accident Commission consisting of three men. They make rules and regulations and work out methods of doing this vocational rehabilitation. For more than three years the work has been successfully carried on in the State of Oregon and we are now in a position where we confidently say that we have done more and are doing more in this line of work than any such organization in the United States.

The problem of vocational rehabilitation is one in which society as a whole has or should have a deep interest. It necessarily follows that each individual and all civic, social, and economic organizations are interested in the development of this work. In our opinion the work of vocational rehabilitation is only one step of an economic procedure that has been recognized by all producers and employers for ages, but until recently not applied to the human element used in production. An individual or company starting in a business or industry takes into consideration the life of his machinery or equipment, sets aside a certain sum for replacement, or annually makes an allowance for depreciation in his machinery or equipment. In the case of machine shop equipment as an illustration, if a part of a lathe be broken, and it may be repaired by putting in a new gear, head, bed, whatever the broken part is, this is rehabilitating

that lathe by physical repair, and saves for a time, possibly many years, the expenditure necessary to buy a new lathe. The workmen's compensation fund is the money set aside to be expended in caring for and restoring the human element in industry.

We do not care to enter into a technical discussion of the loss occurring

Fig. 1.—This man, so badly burned that without special apparatus and persistent scientific effort he would have remained hopelessly deformed, is back at his old occupation in the logging woods.

in industries annually, nor do we care to attempt to show by statistics the annual loss in production by the introduction of new men into an industry. It is well known to all who have made a study of the problem of hiring and firing that it costs an employer considerable money to break in a new employee. The amount, of course, varies with the industry and also with the individual being broken in. As an illustration of some of the work we have done that meets this particular phase I refer to case No. 112,016, an individual who was injured while in the employ of a very large manufacturing plant. He had worked there about eleven years, had seen the plant grow from a small industry to one of the largest ones in the state. In fact, "he had become a part of the concern." His injury to-

tally incapacitated him for the work he had been doing. After interviewing the man and making a study of his past experiences, vocational handicap, home environment, and other determining factors, we made arrangement with the company where he was injured, permitting him to go into the machine shop and receive special training in tool grinding. After eight months of this work the foreman of this particular department reported that the man was highly efficient and should be placed on the payroll with a wage as other employees in the tool and die room. This man has a wife and three children under fourteen years of age. When he was first interviewed he was apparently helpless and was fearful that he and his family would become public charges or objects of charity. The amount expended for sustenance while this man was receiving his apprentice training was \$620. This money was given to the man and his family from the rehabilitation fund of the workmen's compensation fund, and was not considered as charity, but as pay for his work in the shop, so as to make it possible for him and his family to live without the aid of charitable organizations while getting this training.

Consulting statistics on the subject, we find that it costs approximately six hundred dollars per year when a man and family are taken care of by the county or charitable organizations. With the expenditure of our \$620 we fitted this man to support himself and family, and after eight months he began drawing the regular scale for this class of work. To speculate as to what might have been in a state where no provision is made for vocational rehabilitation, we may construct our picture from the daily records of the coroner, the police department, the courts of domestic relations, the industrial schools for boys and girls, and from other civic organizations dealing with the problems of the "unemployable."

We early recognized the fact that many injured individuals may be vocationally rehabilitated by physio-

therapy or corrective treatment as illustrated in Figure 1. This man was a timber faller. A can of gasoline near where he was at work exploded and burned him severely. For a time his life was despaired of. The burned portion covered his entire body, hands and arms. The breast and throat were very badly burned. During the process of healing the scar tissue drew his chin down until it was impossible for him, when he became ambulatory, to see anything above the level of his eyes. Dr. Dillehunt prescribed treatment in the physiotherapy department. The expert who has charge of making appliances made the harness the man is wearing, and for some time put pressure on the chin to hold each day what was gained by the treatments. After about three months the man had so far improved that he could read the advertisement of a furniture store on the top of a five-story building across the street from the office. After about five months' treatment, though not from the date of injury, the man returned to his former occupation in the logging woods. This was made possible by the physiotherapy or corrective treatment.

We have been able to show wonderful results in this work very largely due to the fact that we have not been handicapped by legal regulations or wordy laws that are hard to interpret or understand. The act makes it possible for the State Industrial Accident Commission to rehabilitate the man and intrusts to the members of the State Industrial Accident Commission the authority of making rules and regulations for the proper administration of the law and the efficient rehabilitation of the men. The members of the State Industrial Accident Commission in the state of Oregon, when given this authority, de-

cided that they would as far as possible eliminate all red tape. With the first case reported and investigated we began discussing the reports and

study of the case and is intended to uncover a number of conditions existing, particularly his present environment and his past experiences.

He is then called for an interview and if he desires vocational rehabilitation and said vocational rehabilitation cannot be accomplished by physiotherapy or corrective treatment and may be accomplished by training in school or on a job, the man is assigned to a school, factory, mill or other industrial work so that it may be possible for him to be trained in his chosen field. In the state of Oregon use is made of all existing institutions such as the agricultural college, the polytechnic school, business colleges, etc.

A case to illustrate the methods is shown in Figure 2. This

Fig. 2.—Even a broken back in this injured workman has not proved such a handicapping experience as to prevent his restoration to physical usefulness and a new mental world through being retained in architectural drawing.

young man had two years training in a city high school. Through the war period he was working in the ship yards and fell from a scaffold. His back was broken. After fourteen months in a hospital his case came to the attention of the vocational director and a number of visits were made. The mental condition of the young man was at that time the big problem. It took a number of visits and many heart to heart talks to get him to see the brighter side of life. After discussing the possibilities it was decided that he would take up drafting and architectural drawing. A teacher was provided and for about three months the teacher called twice a week. A table was built as shown in the picture and the young man began his work. While this was going on the vocational director discovered that a possibility of some improvement by a surgical operation. The surgeon examined the man and after a month or two decided that it was possible to get this man to walk by certain surgical operations if successful.—(Continued on Page 576)

forms necessary for his case. From this and following cases we soon developed a simple form for keeping records of all cases. The commissioners have established as a working basis for vocational handicap the period of forty months. When the final award is made and the man is reported as being entitled to forty months compensation, we assume that he is vocationally handicapped. This man is then sent a questionnaire.

Fig. 3.—This man, with permanent and serious injury to head, back, and leg, has during the period of training earned his living and paid for his equipment, and this in the face of a physical condition at first held untrainable.

(Form No. 202-A). He is asked to fill this out and return it. This is for the use of the Director of Vocational Rehabilitation in his preliminary

and after a month or two decided that it was possible to get this man to walk by certain surgical operations if successful.—(Continued on Page 576)

Practical Methods for Removal of Dust and Fumes*

The Chemist and Engineer Work Jointly to Detect and to Remove at Its Source the Health Hazard from Air Pollution

By H. H. VALIQUET, CHICAGO, ILLINOIS.

PRACTICAL removal of dust and fumes comes through knowledge and through the special study of each problem presented. Nothing helps more to the end in view than similar problems and it goes without saying failures often teach more than success. One familiar with fan applications in the last fifteen years knows the science of practical application has taken a new step with the more general use of instruments for accurate duplications of flow of gases.

This has developed a coefficient of 0.71 for wood working hoods under average conditions or in other words one-half of the potential or (total energy in this case) that existing at point of connections to hood is converted in velocity of flow and the remaining half is required to overcome losses. This coefficient is considered one of the practical values used in the new step of fan application to dust removal.

On the other hand, besides the accurate determination certain empirical ratios have been accepted as good practice, such as ratio of one to twenty or area of hood connections to area of hood, and forty per cent over-all efficiency for transposed draft in indirect applications of air jets for spray—both exhaust.

The practical tinsmith is in a position, as he always has been, to say such a job will take forty horse power because one over the other side of the street is twice as large or has twice the number of openings and takes 80 h.p., or better still a good blow pipe man can say you have twenty openings and need $2\frac{1}{2}$ inch suction, will lose $1\frac{1}{4}$ inches on the intake, two inches on the line, $1\frac{1}{4}$ inches through a separator and consequently need 10,000 volume and require 15 h.p. motor.

Most of this data is available for the asking from the larger fan companies, but it rests with specialists to treat special cases of application.

Take even a simple case of grinding or polishing of metals—how many engineers or even men with practical experience combined with engineering, such as most members of the National Safety Council, specify hoods adaptable to the different heights of men or arrange exhaust equipment with an eye to conserving waste heat? There are two types of installation where dust laden air is rendered clean and returned to the room conserving heat. All installations of this nature

where we must look to these chemical engineers for information to make an installation effectual and truly practical.

In many cities there should be some movement on foot to eliminate the dust of the streets and city air in general. This is neglected to a large extent and becomes more noticeable during March winds.

On the subject of practical methods of dust and fume removal, let me touch on some more recent branching out along these lines. In handling exhaust from granite and marble surfacing machines or hand work on this material, three installations have been made in three years. One recently in Wisconsin having eight 4-inch openings for hand lettering, two 8-inch on surfacing machine connections, and five h.p. for this work is inadequate, from my experience, as $2\frac{1}{2}$ h.p. per each four 4-inch openings or each 8-inch opening is the standard set by tests at Barre, Vt., in which I took part. The surface has been just scratched in this field of dust elimination.

In paint spraying work the field is just being covered by the indirect or aspirating method of fumes exhaust. This costs three times as much as the present direct method of drawing paint-laden atmosphere over motors and fans, but eliminates consequent hazards and uncleanly results.

Paint should be drawn downward, whether dry dust in rubbing down castings or in spraying wet pigment. This is contrary to the practice in the average factory.

The core oven is another neglected source of air pollution that is coming to receive something approaching proper attention. The doors should be hooded at top and 250 to 500 feet velocity maintained over the full hood area. The hood should extend three feet in front of door and along the full openings over the oven. The removal of castings from hot molds gives another example of dust hazard sadly neglected.—(Continued on Page 574)

Fig. 1.—An excellent example of blow pipe installation and buffing wheel hood, well trapped, in plant of the Victor Talking Machine Company.

could be so adapted as to effect a saving of air heat, but sand blast, painting, rubbing down of machinery and handling air from nippers or teasel gigs are successfully accomplished in this way.

With due credit to these practical steps in advance of this dust eliminating hazard, there is still a greater need for the help and knowledge of the government bureaus, especially that of the Bureau of Chemistry and Bureau of Mines.

Cyanid baths and acid exhaust, the handling of carbon dust, of grain, of hydroscopic material like malted milk or soda ash—here is a field where chemistry and mechanics are consolidated. Estimation of the parts of oxygen present per part of dust, consideration of factory of temperature and humidity mean something to the chemist and brings the practical consideration of the problem to a point

*Address before midyear safety conference, Engineering Section, National Safety Council, Chicago, April 17, 1923.

Health Administration in Virginia

Public Schools

The University of Virginia Gives for Teachers a Course in Health Education that Leads to a Bachelor of Science Degree

BY MARY EVELYN BRYDON, M.D., DIRECTOR OF THE BUREAU OF CHILD WELFARE, STATE BOARD OF HEALTH, RICHMOND, VA.

THE authorities of the Commonwealth of Virginia believe that it is the function of the state department of education to direct the instruction of the child; and that it is the function of the state board of health to help the child to become physically fit to receive the greatest possible benefit from the educational process, in order that the children of the state may develop into strong and efficient citizens with the right attitude toward health as one of the most valuable possessions to be acquired. The increasing attention directed to the proper care of children during infancy and early childhood will in time greatly improve the average health condition of pupils entering the schools, at present so universally deficient. For this generation, however, the best that can be done for the school child is to correct defects when possible, make the environment sanitary, and train the future fathers and mothers in healthful habits and ideals.

The problem in Virginia has been to supply to the children in its many rural schools the physical inspection and health instruction that is now generally available to dwellers in urban communities throughout the country. The work now carried on by the state board of health and the state department of education is in compliance with the provisions of Chapter 327, Acts of Assembly, 1920, known as the West Law, which provides "That after the first day of September, 1923, all pupils in all the public elementary and high schools of the state shall receive as part of the educational program such examinations, health instruction, and physical training as shall be prescribed by the State Board of Education and approved by the state Board of Health." and that "The state Board of Education, with the approval of the State Board of Health, shall establish regulations whereby on or after September, 1925, no applicant may receive a certificate to teach in the schools of this state who does not

first present satisfactory evidence of having covered creditably an approved course in general physical education in a training school or course for teachers recognized by the State Board of Education as a school or course in good standing." During recent years, Virginia has suffered, as has every other state, from the diminishing percentage of doctors. When the West Law was passed, its proponents knew that there were not in the rural sections of the state enough medical men to make examinations. A plan was therefore formulated to utilize the state's teachers in promoting the health and vigor of pupils and in preventing the spread of communicable disease by the following program:

(a) The teachers shall be instructed in the fundamentals of safeguarding the health of their pupils by securing healthful environment, and by inculcating health habits.

(b) The pupil shall receive an annual health inspection to determine his physical fitness.

(c) Any physical defects thus brought to light shall be corrected; and, since the logical persons to encourage corrections are the public health nurses, it is proper that the employment of such auxiliaries to education should be aided by means of financial assistance to counties employing them.

(d) After the children have had their physical defects corrected, they shall be returned to school to receive health education and physical education as a part of their course of study.

A Joint Program

This program is carried out by the following means:

(a) 1. Health instruction for prospective teachers at normal schools and other teacher-training institutions under the joint supervision of the State Board of Health and the State Board of Education. 2. Establishment of a correspondence course in physical inspection and school hygiene conducted by the State Board of Health and the State Board of Education.

(b) Requirement of physical inspection of all pupils by the teachers, under supervision of a school nurse or health supervisor where there is one, within three weeks after the opening of the school; the individual reports

of these inspections sent to the parents; tabulated reports sent by the county superintendents to the State Board of Education.

(c) Promotion and supervision of public health nursing by the State Board of Health, especial emphasis being laid upon supervision of health work in the public schools until the teaching force is sufficiently organized by the State Board of Education to relieve the nurse of this duty; and the promotion of correctional work in the rural districts for the purpose of correcting the physical defects brought out by the inspection. This includes, according to the stage of public health development in the various counties, the following: Dental clinics, adenoid and tonsil clinics, eye clinics, orthopedic clinics, nutrition classes, and systematic measures for the elimination of intestinal worms.

(d) Financial aid by the State Board of Health to assist counties in establishing nursing services and correctional work.

(e) Supervision by the State Board of Education of: (1) Instruction in physical education of prospective teachers in normal schools and other institutions having teacher-training. 2. Physical education in the grades. 3. Financial aid to assist counties in establishing physical education directors in the schools.

As a beginning of the work assigned to the state board of health, a course of five lectures on physical inspection and school hygiene—all that could then be crowded into their already full curricula—was given to the normal schools and some of the colleges of the state. This number was later increased to ten, as the colleges and normal schools became interested in the problem and began to realize the full import of the provisions of the West Law.

Last year twenty-five out of thirty-seven colleges and normal schools had courses for prospective teachers dealing with school hygiene, physical inspection, and physical education. These courses are required to have a minimum of thirty-six hours a year; and eleven of the schools have exceeded this time requirement. Two of the normal schools are for colored teachers. The courses are also given in all of the nine summer normal

schools; and in the extension work carried on by three of the institutions.

The culmination of the teacher-training side of the work was recently reached with the deans of the University of Virginia, who, recognizing the need for college-trained health instructors for the teachers of the state, recommended to the president that the University should grant a Bachelor's degree in Health Education. This recommendation was accepted by the faculty; and the course of study leading to this degree will be offered for the first time at the opening of the fall session of this year.

Teaching by Correspondence

Another difficult problem to be solved was that of the teachers already in the schools who were required to fulfill the conditions of the West Law. As it was not possible for all of these to avail themselves of the courses given in the higher educational institutions of the state, a "Health Manual for Teachers" was prepared in cooperation with the teacher-training department of the state board of education, and preparations made for a correspondence course in physical inspection and school hygiene. This course is credited by the state board of education only on new first and second grade certificates; and on the renewal of any certificate issued prior to July 1, 1923. Holders of collegiate professional, collegiate, normal professional and special certificates issued prior to July 1, 1919, are permitted to satisfy the requirements of the West Law by securing credit through this correspondence course.

The course consists of twelve lessons and a final examination covering the following subjects: physical inspection of school children; school sanitation, or control of communicable diseases; personal hygiene; prevention of accidents and first aid to the injured; essentials of physical education; the teacher's health; and methods of teaching hygiene. No fee is required for the course, the students merely paying the postage and buying their own texts.

So much for that part of the problem relating to the instruction of teachers. What, then, is being accomplished in the schools?

After hearing that the teachers must make an inspection of the children, naturally, physicians and other well informed people will protest that teachers, as a class, are not able to make physical inspections approximating accuracy. That is indisputable if by the term, "physical inspection,"

is meant such an examination as would be made by a trained physician; but it does not require years of training in medicine to determine whether a child's sight is obviously defective or his hearing impaired. An ordinarily intelligent person can determine whether a child is a mouth or nose breather, and knows that if exclusively or principally the former, there is something wrong requiring medical attention. The distinction that is made between "inspection" and "examination" has been illustrated by the simile of a person buying a desk. The prospective purchaser looks the desk over, feels it to see if it is well finished, opens the drawers to see if they run smoothly, pushes against it to see if the joints are solid, etc. That is inspection. If it is found that one of the drawers will not open properly and that there is a rough place on the surface that would interfere with writing, the desk is then sent for "examination" to a cabinet-maker who can soon determine why these defects exist and the proper method of correcting them.

"Inspection" of school children can be done by teachers, who will detect a large proportion of the more serious defects in their pupils. The teacher can then recommend to the parents that the defective children be sent to a physician who can "examine" them and take any necessary steps for effecting the needed repairs.

The state superintendent of public instruction has instructed the division superintendents to set aside a day in the fall for inspection of the children. This is an advantage that could not have followed had the state board of health been in sole control of the work. A distinct advance in this direction has been made recently when the state board of education and the state board of health jointly employed a supervisor of health work in the rural schools.

On the appointed day each year every teacher in the state tests the vision and hearing of the pupils; inspects their teeth; and weighs and measures them for comparison with standard height and weight tables. Teachers are not yet required to inspect throats; but the better trained teachers do this also when no nurse or doctor is available.

When the inspection is completed the teacher sends a notice to the parents of all children found to have defects. On the reverse side of this notice is a letter from the state commissioner of health, setting forth the danger of neglecting the health of children.

The focusing of attention on the ultimate physical fitness of the child, on the necessity of becoming healthy and keeping healthy, is the outstanding objective of this work. Already the required inspection has resulted in an increasing intelligent interest in the child's well-being on the part of the teacher; this is shown by the fact that some teachers have secured 60 per cent of correction of defects. These corrections must result in a marked lightening of the labors connected with the teaching process, for both teachers and pupils.

Method Commands Attention

Tabulated reports of the results of inspection are made to the county and state superintendents. The individual grammar and high school record cards, which follow the pupils from room to room and from school to school, have on one side a form for recording academic grades and on the reverse side a form for the record of physical inspections from year to year.

The result of the first inspection showed such a large percentage of dental defects that the next step in advance was obviously the establishment of clinics for the correction of these defects.

At present there are ten whole-time dentists doing this work in the rural districts under the supervision of the state board of health; and during the fiscal year ending September 30, 1922, they treated 8,135 children, involving 28,805 operations. Each dentist holds his clinic in a school and remains there as long as needed, then passes on to another. A fee of fifty cents is charged for each operation and the state board of health and the county organization responsible for the clinic make up the deficit.

Tentative figures for the physical inspection of school children for the year ending June 1, 1922, are shown in Table 1. It shows that more than 58 per cent of the school children in

TABLE 1.—PHYSICAL INSPECTION OF SCHOOL CHILDREN—YEAR ENDING JUNE, 1, 1922

	Total for Counties	Total for Cities	Total for State
Enrollment, 1921	414,610	110,246	524,856
Number inspected	193,099	143,433	336,532
Defective eyes	39,916	4,283	44,199
Defective hearing	13,236	1,196	14,432
Defective teeth	108,252	24,526	132,778
Defective tonsils	7,367	1,834	9,201
Underweight	20,287	4,058	25,345

the state were inspected during this period.

Summary of Progress

As a result of the passage in 1920 of the West Law the Commonwealth of Virginia has in operation a program that provides for training teachers in physical inspection, health education and physical training. Prospective teachers receive this training in twenty-five schools and colleges of the state. Twenty-three of these give to these subjects thirty-six or more hours of instruction. The teachers in the field who are unable to receive instruction otherwise are reached by a correspondence course. In the schools and colleges 1,628 pupils were taking such a course in the session of 1921-1922; in the two years since the correspondence course was established, 1,689 have enrolled. The University of Virginia has undertaken to give, beginning in the fall of this year, a course leading to the degree of Bachelor of Science in Health Education.

Each year the children in the schools are inspected by the teachers and nurses and a great many of the defects discovered are corrected by means of follow-up work conducted by the school nurses, or the Red Cross social workers, or the teachers. Thirty-one of the hundred counties of the state have nurses for school work and receive aid from the state.

Virginia has embarked on a policy that promises to become very effective in dealing with the problem of health in the rural schools.

Physical Examinations of Teachers

All teachers in the public schools of the District of Columbia are required to undergo a thorough physical examination before their appointment.

The school medical inspectors recently examined 142 applicants for teaching positions in the public schools, 57.7 per cent of these were passed as physically eligible, 38.7 per cent were passed conditionally, subject to reexamination at the end of their probationary appointment, to determine whether minor defects had been corrected, 2.8 per cent were rejected temporarily due to more serious defects pending correction, and .7 per cent were rejected permanently on account of permanent serious physical defects.

Of the applicants examined, 21.8 per cent had defective nutrition, 15.4 per cent defective vision, 8.4 per cent defective teeth, 3.5 per cent diseased

tonsils, 2.8 per cent enlarged thyroid, 2.8 per cent cardiac conditions, 1.3 per cent defective hearing, 1.3 per cent pulmonary disease and there were .7 per cent each having the following conditions, exophthalmos, nervousness, hay fever, and serious constitutional disease.

The Henry Street Nurse

World Wide Photos

The future of public health nursing is largely an extension of the ideas and ideals growing out of the work of Henry Street Settlement and contrasts between past conditions encountered by the Henry Street Nurse and the present situation mark the milestones of progress in neighborhood service. Everyone is glad that the Henry Street nursing service now has an administration building worthy of the enterprise. The picture shown is reproduced from a painting, the work of the artist Reni Mel, presented by the French to the American Legion.

Survey Needs for Community Dental Service

A report of a survey of dental needs and facilities in various cities of the United States with special reference to a dental program for Chicago contains many interesting statements. It is estimated that 20 per cent of all the teeth of school children are in a state of decay; only about a third of public school children are found ever to have been to a dentist; while the large number with crooked or irregular teeth makes it desirable that every child be seen not later than the age of five by a dentist with some training in orthodontia.

Michael M. Davis, Jr., the author of this report also found that the need of oral surgery for adults, exclusive of extractions, was comparatively

rare, not over one per cent requiring it, and that a complete set of false teeth were required for a small proportion of adults, not over two per cent.

It is estimated that there are at present eight hundred fewer dentists in the United States than in 1920, "owing to higher standards for entrance requirements now being introduced in the dental schools. The combination of a reduction of students due to the war and the further reduction due to the lengthening of the course has created a particularly serious scarcity of dentists at the present time. It is difficult for the dental infirmaries to keep their staffs up to full strength." There is at present one dentist to about 2,400 population.

Legislation has provided for the licensing of dental hygienists in twelve states. The total number of graduates from all existing schools now numbers about 470. The total number in last year's classes was 136. "There is considerable apprehension that the dental hygienists will be absorbed as quickly as they are graduated into the offices of private dentists, as the majority have been so far."

Dr. Davis believes that adequate dental facilities for a community cannot be built up on the basis of private practice; that preventive dentistry in particular cannot be developed as a part of private practice; and that facilities for dental work supported by public or semi-public bodies must be depended on to provide dental facilities for a large part of the adult population and to furnish almost all the preventive facilities needed for the children.

Comparison shows that the dental facilities of Chicago are far less than those of many smaller cities. The following system is recommended to meet this need: (1) A central institution of approximately 60 chairs; (2) four branches, approximately thirty chairs each; (3) school clinics (for curative work), located in outlying districts and supplementing the branches; (4) dental prophylaxis and instruction in oral hygiene for all school children, to be done in the school, according to the Rochester plan, by traveling squads of hygienists under centralized dental supervision; (5) the central institution to be under an independent board, but affiliated with medical and dental education and with a general hospital; and (6) dental research to be an integral part of the program, and provided for in the facilities of the central institution.

Maternity Homes and Baby Farms in the State of Texas*

For Improving the Conditions Pertaining to Women and Infants the Service of the Obstetrical Clinic Must Be Improved and its Service Extended to as Many Women in the Community as Possible

BY MRS. THEO. REESE, STATE BOARD OF HEALTH, AUSTIN, TEX.

THE status of maternity homes which I have visited and made reports on is not ideal. It is impossible to anticipate too much from these homes since there have only been nine months of active field work in this line, but I find that most of them are willing to accept advice and improve most of the existing conditions that are contrary to law.

The ultimate aim of a maternity home should be to preserve health and return the patient home in an excellent physical condition. At the same time the environment of the maternity institution should be such as to exercise the right sort of moral influence over the patient.

If these homes are to protect her in society, her health should be of vital interest to herself, family, and state. This can be accomplished only by having doctors or obstetricians of ability to supervise and do the work in these homes. Most of the homes permit the girl to select her own doctor, or the home has on its list several doctors, any of whom may be called. A very few have an obstetrician in charge who does all the work, or at least the supervision, which would assure good service. It is apparent that a maternity home of this sort should be equal to a maternity hospital open to all classes of people.

Most of the private maternity homes are not as well equipped as the average public institution. Therefore, the work in a public maternity hospital should be better than the work in a private maternity hospital for this class of girls. The type of private maternity home referred to is one opened up by some lay person, as are the larger percentage of these homes. For example, in several towns I found maternity homes conducted by women who previously kept disorderly houses. To them it was of commercial interest and not for the welfare of the unfortunate. I mention this deplorable condition so that prop-

er action may be taken to stop issuing licenses to these people by the local authorities. In one instance one of these women who was refused a license to operate in her own town, to evade the law, moved out of the town limits and secured the approval of the county authorities who were not familiar with her past.

Maternity homes should be properly manned by competent nurses and supervised by an obstetrician conscientious and interested in his work and in the social life of these girls. This combination will make a good maternity home.

It is almost impossible for one inspector to accomplish all desired by the state. The city board of health should cooperate with the state health department in weeding out, and assisting in the development of a condition where the mother will have proper attention equal to that given in any hospital. State and city officials are not doing their duty to these unfortunate girls unless these maternity homes are properly conducted.

Baby Farms Flourish

With the question of maternity homes, it is necessary to give some attention to the problem as to what becomes of illegitimate children. Unfortunately, our own state law does not specify what shall be done with these children. Some of the so-called maternity homes for illegimates permit adoption of babies directly therefrom, while others do not. A few homes for these illegitimate and abandoned babies are run by competent and responsible individuals, such as Faith Home, Houston, Hope Cottage, Dallas, and the Texas Children's Home and Aid Society, Fort Worth, through which adoption may be made. Personally, I believe that the maternity and founding institutions should be separated if we hope to reach the highest point of development. As is well known, some women confined in maternity homes keep their babies.

The condition in some of these

homes is hardly appreciated by those who have never visited them. In one instance a keeper of a home when prosecuted for procuring, openly boasted that "she sold babies born in her house, and sometimes if she could not sell them she gave them to the garbage man or anyone else who happened along." Another woman who offered to buy babies from girls confined in a hospital placed at least one child born in her maternity home with a prostitute. These are doubtless extreme cases. It is undoubtedly true, however, that in many cases the commercial factor enters into the question of disposition of the child.

What we have to consider here is the question of the unwanted child. Frequently the unmarried mother does not want the child, or her family does not. She goes to a maternity home for the purpose of getting rid of the child. The infant is deprived from birth of all social safeguards ordinarily thrown around the child of married parents. The matron of the maternity homes, if she is not especially scrupulous, disposes of the baby as seems most convenient or profitable to her. But if she is conscientious, she will place the child in the hands of people whom she believes are capable of raising it properly, though in such cases certainly there is far too little assurance that the home is really a proper one when not obtained from a responsible founding institution.

Placing of children requires careful investigation and supervision by intelligent workers. When one examines the question closely, it is difficult to escape the conviction that the public does not accord the illegitimate child the same right to a fair start in life that it thinks other children should have.

The baby peddler, the free lance man or woman whose means of livelihood is the placing-out of infants, usually depends upon these maternity homes for the supply of children. By the terms "baby peddler" is not meant an organization, supported by charita-

*Read before the Twelfth Annual Meeting of the Texas Conference of Social Welfare, Dallas, Texas, October 15-18, 1922.

ble contributions, whose work it is to find homes for children, but men and women traveling throughout the state, not responsible to any private or public body, who deliberately traffic in the offspring of unmarried mothers. That they operate under the guise of a religious cloak does not make their work the more commendable. One such individual who abandoned his own children to a child-placing society several years ago peddles children for what he terms expenses, though these expenses include a liberal allowance for car fare when he travels on railroad passes.

Before these conditions can be improved, certain changes will have to be made in the laws relating to maternity homes and illegitimate children. If the statutes provided, as it is now the law in some states, that no mother should be allowed to give up her baby until it was at least three months old, except to safeguard the life of the mother or child, and several homes in Texas do require this, we would be able to strike at the root of the difficulty which is the easy abandonment of children by parents. We must face the facts that to allow a mother, though unmarried, to desert her child at birth, is to encourage a shifting of responsibility which is highly undesirable both for the mother and the child. In addition to this there should be strict regulation by state authority of all individuals and organizations engaged in placing children. The state should set up certain standards required of everyone who undertakes this important work. Much is also to be said in favor of a law which would make the state automatically the guardian of every child born out of wedlock.

Homes for babies should be of the very best, supervised by those who believe that the waif is entitled to life, liberty, and happiness, the same as any other child. Persons who do not believe this, should not have supervision over these little unfortunate children. We all know they suffer enough and that they should not be bartered on the streets like cattle. Social workers should strive as never before and abolish homes that are bartering these children and should properly place the children so that their future will not be so dark.

A High School Board of Health

Though not a recent innovation in the school health and hygiene program, the organization of Health Clubs and Student Health Societies heretofore has been confined to the

elementary grades. With a few adaptations and changes, the work of the Health Club can well be carried over into the ninth, tenth, eleventh, and twelfth grades and may prove a very potent factor in modern high school life. "Self-imposed rules of health and hygiene are of more permanent value than those thrust upon us by others. Self-instruction in personal health can thus be developed and, not infrequently, instruction can be combined with service. The high school student at this age demands some work which will bring a sense of self-reliance, initiative and self-control. He no longer accepts, *"sans contrainte,"* the commandatory rules of health instruction as given him in the lower grades. He wishes to investigate, to learn for himself, if, at this significant stage of life he is awakened to the value of regular personal health habits and clean, wholesome living as it relates to himself, to his class, school, and community, he will be well started on a path of ideal citizenship. In fact, no better training for citizenship may be conceived than the organization of such work in the high school.

In the Pittsburgh, Pa., High School, the Health Club work has been made a part of the Student Government Organization and effectively functions as a student activity. This Student Board of Health is composed of one representative (known as the Health Officer) from each report room, popularly nominated and elected by his or her respective class. These representatives meet twice each month to discuss matters pertaining to the health and sanitary conditions of their particular rooms and of the school and community in general. Any measures of specific value in effecting better living conditions in the school are considered. Such details as proper ventilation and temperature, correct lighting, sanitation of class-rooms and wash-rooms are discussed. In addition to the consideration of local interests, a definite study of some phase of health is considered at each meeting. Such subjects as proper food, clothing, bathing and personal habits, safety and first-aid, etc., are discussed. Thus, each health officer or representative acquires a new perspective each week. He, in turn, imparts the knowledge gained to his respective class the following day at the regular class meeting. It follows that the individual student will, very often, be awakened to a keener interest in personal and social problems thus presented by his classmates than would be the case were

the same problems presented by the teacher.

He feels a sense of personal responsibility in keeping or helping to keep his room "one hundred per cent" sanitary and himself "one hundred per cent" healthy. The Student Board of Health functions best as a purely Democratic organization, conducted by the students themselves. However, the supervision of a faculty member is necessary to the success of the work. A teacher who has an earnest interest in the subject of health and the proper promotion of health habits should be appointed by the principal as the faculty advisor of the Student Health organization. Constant inspiration and interest on the part of this advisor is necessary to enthuse the student health officers and to promote the best interests of the Board.

Narcotic Drugs and the Penal Institutions

Significant reports have been submitted on the effect of the narcotic drug situation on the New York State penal institutions. The first of the statements was in the annual report of the New York State Prison Commission, submitted in February, 1922:

"The whole situation as to the handling and treatment of drug addicts in New York City is a deplorable one. The treatment of the addict as a criminal is certainly not effective, as is shown by the statements of repeaters: of the 'cures' effected by the Riker's Island institution, for example, 30 per cent were repeaters and 10 per cent returned for a third treatment during the year."

Included in the annual report is a special statement by Ernest S. Bishop, M.D., consulting physician of the New York State Prison Commission. Dr. Bishop acknowledges that the penal institutions have failed in their treatment of addicts, but says that they are not to be blamed. The care of non-criminal addicts is not properly their function; it is in the province of institutions other than penal. The failure of these other institutions to bear the burden has "tended to throw under an unfortunate criminal classification and into penal handling a large number of the non-criminal addicted, not only complicating the situation and problems in the penal institutions but engendering great sociologic and economic and personal problems."

The inadequacy of medical treatment is a serious matter, according to Dr. Bishop.

Organizing to Salvage the Mental and Nervous Derelict

The Mental Hygiene Movement Expresses the New Understanding of Social Maladjustments

BY JOSEPH SMITH, M.D., ATTENDING PSYCHIATRIST, BETH ISRAEL HOSPITAL, AND JACOB A. GOLDBERG, PH.D., DIRECTOR, COMMITTEE FOR HEALTH SERVICE AMONG JEWS, NEW YORK CITY.

PRESERVATION of the mental health of the individual is coming to be recognized as one of the most important functions of society. Unfortunately, to suffer from a disordered mind has been a stigma, and this stigma has spread even to those who concern themselves with the problem itself. This sentiment is still wide-spread and places enormous obstacles in the way of constructive work. It undoubtedly accounts for the reluctance of socially minded and philanthropically inclined men and women to support movements and organizations whose purpose it is to preserve mental health and to redeem the mentally ailing. Laymen still think of mental disorders as only those which are characterized by more or less actively antisocial behavior, rendering those afflicted a source of danger to themselves or to others. There is another group of mental disorders—less menacing in appearance, but of utmost importance to society—known technically as psychoneuroses, including hysteria, neurasthenia, psychasthenia and other less well defined types of psychopathic personality.

For the individual the problem of the preservation of mental health involves the selection of a mode of life appropriate to his particular abilities and handicaps, and the adjustment of the outlets for instinctive cravings to the limit set by a social manner of living. The development of the mental hygiene movement indicates the growth of a deeper insight into the causes and effects of mental maladjustments arising out of the complexity of modern life, including the whole field of education, in the home and school; the matter of re-

ligion, marriage, occupation and so forth. The total number of persons in the country who are suffering because of mental maladjustments cannot even be estimated with any degree of accuracy. We do know the number of such persons who are patients in state hospitals for the insane, but we can only vaguely guess

in need of medical attention. Together with these two items—the determination of a statistical average and the development of facilities—there would result a better understanding of the causes, of methods of treatment and social adjustments fundamental to the improvement of those mentally and nervously sick.

The Committee for Health Service among Jews functioning as the educational division of several organizations interested in health problems, has initiated a mental hygiene educational campaign among Jews, with the distribution of literature, lectures in synagogues, factories, lodges, schools, settlements, etc. In addition, diagnostic clinics have been opened and those applying are examined by a psychiatrist or neurologist and advised as to facilities for treatment, hospitalization, social adjustments, etc. Table 1 presents the diagnoses of 250 mental hygiene patients examined during the year of their activity.

The figures indicate that approximately 15 per cent of the patients were mental defectives, 15 per cent suffering from some psychosis, and the remaining 70 per cent psychoneurotics, epileptics, etc. Statistics of this kind gathered over a period of several years in different parts of the country would throw much light on the relative incidence of various forms of mental and nervous disorders.

While mental and nervous troubles may have their roots in early life, usually it is not until adulthood is reached that the problem of adjustment becomes so severe and trying that the patient and his family find it necessary to have recourse to special clinics and hospitals. Approxi-

Service to Redeem the Mentally Ailing

ANOMALIES of personality, whether temporary or permanent, are explainable through the experience of the individual. They are as often due to stupid handling as to inherent constitutional defect of the individual patient.

The mental hygiene movement seeks prevention, or at least amelioration, through industrial and social adjustment, and institutionalizes only the socially unadjustable. The stigma that has in the past retarded progress in this field has no place in the mental hygiene program.

The lack of physical or moral stamina, or of courage in the crises of life, instability, emotional unrest, and general inadequacy under ordinary conditions, are proper materials for professional consideration in the hands of the psychopathic clinic.

at the number of those included under the term psychoneurotic.

An intensive educational campaign over a period of several years would help to determine the incidence of these mental and nervous disturbances, at least within the confines of a selected number of communities. Concomitant with such a campaign there would have to be an increase in the arrangements for treating and hospitalizing such as might be found

mately 50 per cent of the patients were between the ages of twenty and forty years, which would seem to bear out this conclusion. It is, of course, recognized that many forms of mental and nervous disturbances do not as a rule become aggravated until early adulthood, and that with the increasing death rate after forty years, there would come a decrease of the occurrence of these ailments. Nevertheless, the social significance is that the mentally and nervously ailing are found largely in the age groups which are considered the productive periods of life, and therefore, socially the most important and useful.

The 3 per cent immigration law has had its effect in limiting the number of recent arrivals who, suffering from mental and nervous ailments, apply to clinics for advice and treatment.

The nativity of the patients is in approximate agreement with the reports of the Immigrant Division of the Department of Labor over a period of years. Over 25 per cent of the patients were native born.

The occupations of the patients examined were representative of the trades and industries to which Jewish men and women turn for a livelihood, especially such as are found seeking medical advice and treatment in the clinics of the city.

The above data present the picture of a large portion of the patients who frequent dispensaries, clinics and hospitals, seeking in each place some panacea for their disturbed and troubled mental and nervous systems, and only infrequently finding the balm for which they look. This is not due altogether to the difficulty of the patients to adjust themselves, nor to any innate moral or other laxity on their part. Primarily, it is an indication of two things: the inability of medical

science alone to cope with many of the problems presented by the patients, and the lack and shortcomings of community facilities for the care and treatment of such patients.

Mental Hygiene and the Jew

It has long been recognized that there are mild mental cases which do not require commitment to a state hospital or to a sanatorium; this is similarly true of certain abnormalities of conduct among children and adults which may bear the seeds of a future psychosis. To cope with such conditions the State Hospital Commission has organized a number of out-patient clinics, placing them in different sections of the state.

The Jewish patient often presents a problem which requires special attention. By virtue of racial characteristics, tradition, difficulty of adjustment to a new environment, a language difficulty, the aversion to and fear of state or municipal hospitals, and other matters peculiar to the Jew, especially if he be of recent immigrant stock—for all of these reasons the Jew must be considered as a special problem if success is to attend the care and treatment of the mentally or nervously ill. The mental hygiene clinics of the state hospitals are as a rule shunned by Jews, and for this and other reasons clinics with Jewish psychiatrists and neurologists in attendance are apt to achieve a larger measure of success. The following case histories indicate what service it has been possible to render in mental hygiene clinics in which patients and doctors, as well as psychiatric social workers, were Jewish; also what further accessories are necessary to meet the problem of adequate mental hygiene care and treatment for large numbers of ailing Jews.

Case 1.—W. B., a young girl of nineteen came to this country from Russia with her family a few months ago. On the first day of her arrival in New York, following an argument with members of her family, she left the house, wandered about the streets and accosted a stranger to whom she complained that she was without a home and was penniless. She was directed to an organization interested in immigrants. There she related a story that she had been married in Russia, had no relatives in this country, etc. A few days later she was seen by a psychiatrist at her home. Her parents stated that since childhood she had been willful and disliked her family. She kept her face covered with her hands, answered questions evasively, expressed a desire to leave her home and take up nursing or some other occupation which would take her out of her environment. She was found to be obstinate, refused food

and would have nothing to do with her family, and thus presented a complicated problem. To send her to a hospital for observation would have meant her eventual commitment and deportation to Russia, where she had none of her family left. With the aid of a social service worker of the organization for immigrants she was placed in the care of a distant relative in New Jersey and an attempt was made to find a suitable position for her. In other words, the patient was met on her own ground and no violence was done to her personality. On the contrary, friendly relations were established and she is being guided and helped in the solution of a family conflict and a conduct disorder which had its inception in early life. For the past few weeks she has been regularly employed as a helper in a hospital.

Case 2.—Mrs. A. is a married woman of forty. She is intelligent, works hard, keeps her house neat, her children are well taken care of and she takes pride in her home life and her work. During the past eight years she has been subject to repeated attacks of depression and mild excitement. These attacks last a number of months. She becomes impatient, neglects her house work, is abrupt and rough in her manner, scolds and gets excited, leaves the house and runs into her neighbors' apartments or out on the street and walks about aimlessly. She becomes sexually excited, makes demands on her husband; feels ashamed of her conduct and is tortured by the consciousness that she is neglecting her children. She has been under care of a mental hygiene clinic for some years and due to the personal interest a psychiatric social worker has taken in her, it has been possible to lessen the severity of the attacks and to keep her fairly comfortable at home. The stigma of insanity which a commitment would entail, and the throwing of the household into a chaotic state with each outbreak, have been avoided.

Case 3.—A. G. is a patient seventeen years old. About a year ago he developed peculiar spells. From the description given by his parents and by a psychiatric social worker the attacks are unmistakably epileptic in character. Coincidentally there developed also a peculiarity of conduct—fretfulness and irritability. The patient became aggressive, fought his friends, became indolent, and lost confidence in himself. He has been discharged from several positions, principally because of his epileptic attacks. He was treated by many physicians but without appreciable result. His parents are greatly worried, have lost control of themselves and cannot manage the boy. He gets excited over trifles; had an altercation with a neighbor, broke several panes of glass and wanted to throw himself out of the window. On one occasion, after an argument with his father, he turned on the gas. At Bellevue Hospital, the father was advised to send him to Craig Colony, but he is unwilling to have him committed. This case presents a difficult situation; not only is there a serious organic affection which—(Continued on Page 560)

Significance of B.coli in Water in Relation to Health

To Demonstrate Contamination of Water Supplies is not Necessarily to Measure its Danger in Terms of Probable Infection

By W. H. FROST, M.D., UNITED STATES PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

WHAT is known with reference to the significance of B.coli in water in relation to health is the result of so many years of cumulative experience that what can be added by one or two years more of observation can have very little effect upon the sum total. Consequently, anything that may be said properly representing opinion today is in most respects identical with what would have been said some years ago, since the last ten years have seen only one important addition to our knowledge, materially affecting opinion on this subject.

Sanitarians are interested in water supplies primarily as potential vehicles of infection. What they wish to know regarding a water supply is its danger, in terms of the proportion of consumers who will contract infection as a result of drinking it. A knowledge of the water in terms of bacteriology is of secondary interest to them, solely as a means toward the end of forming an estimate of the water's danger.

The facts upon which an interpretation of a bacteriological or chemical examination of water is based are relatively few and simple and are so generally known that they are repeated here merely by way of review.

The first fact of importance is that the real element of danger in a water supply is the pathogenic micro-organisms which it may contain. The second essential fact to be recognized is that we can not at present demonstrate these dangerous pathogenic micro-organisms in water by direct bacteriological processes, because they are present in such exceedingly small numbers as compared to other non-pathogenic organisms. To detect the typhoid bacillus, or other pathogenic bacteria, even in grossly polluted water, is a rare accident; and failure to detect them is by no means proof of their absence.

The third fact essential to the interpretation of any chemical or bacteriological examination of water is that all of the pathogenic micro-organisms which constitute a real danger in water are essentially parasitic, having their natural habitat and breeding places in the bodies of man and other higher animals. Outside of this environment they tend naturally to rapid decrease or extermination, and therefore they are found in nature only in association with comparatively fresh excreta. Moreover, the pathogens of most serious importance are found only in human excreta, not in the excreta of lower animals.

Therefore, since we can not directly demonstrate the pathogenic organisms which may be present in water, our next most specific test for their presence is demonstration of the presence of excreta, especially human excreta.

Evaluate Specific Tests

For many years, with this general principle in mind, chemists and bacteriologists have been working toward specific tests for excreta. The problem is, however, a difficult one, for, while the contamination resulting from a very small amount of fecal material added to pure water can readily be detected by either chemical or bacteriological tests, these tests do not prove that the contamination necessarily resulted from excreta. The most nearly specific chemical tests serve only to indicate broadly the kind and to measure roughly the amount of organic matter present. They do not differentiate between organic matter derived from sewage and that from less objectionable and entirely harmless sources. Similarly, the total numbers of bacteria as determined by gelatin or agar counts, may be taken as indicating roughly the amount of organic matter present which is suitable for the sustenance of bacteria; but, although large numbers of bacteria are present in excreta, equally large numbers may be found in other organic wastes. Consequently the demonstration of excessive numbers of bacteria in water,

taken by itself, does not indicate sewage contamination.

The most nearly specific test for excreta at present available is demonstration of the presence of the so-called "colon bacillus," since this organism is always present in large numbers in the excreta of human beings and higher animals. However, before this test can be considered absolutely specific, it is necessary to prove that the colon bacillus breeds naturally only in the bodies of man and other animals. It is upon this latter point that there has been and is considerable controversy; naturally, since such a proposition can be proved only by exclusion, and even an approximation to proof requires an enormous mass of negative experience.

Notwithstanding the impossibility of absolute proof, a large majority of sanitarians in this country familiar with the bacteriological examination of water would have stated quite positively ten years ago that the presence of colon bacilli as then defined was specific evidence of fecal contamination. They would have based this opinion upon their general experience that these organisms were ordinarily found only in water which was obviously subject to fecal contamination, and that the numbers of colon bacilli found were roughly proportional to the opportunity for direct and continuous exposure of the water to fecal contamination as shown by sanitary survey.

On the other hand, there was a very considerable and highly authoritative minority, especially strong in England and Germany, who held the opposite view that the colon bacillus, though always present in feces, was widely distributed in nature as a saprophyte, and that its presence did not necessarily indicate the presence of excreta. Their reason for this view was chiefly that a large number of studies had shown the presence of colon bacilli on grain, grasses, and fruit, and in soil where the probability of recent fecal contamination seemed extremely remote.—(Continued on Page 557)

Editorials

AS a result of the conference called by Surgeon General Cumming somewhat more than a year ago, the subject of the training of sanitarians has lately occupied a very large share of the atten-

tion of health workers of the country. It is indeed well that we should give careful consideration to the importance of improving facilities for the training of health of-

ficers and that we should make every effort to stimulate the entrance into this field of the large number of men who are needed to fill it effectively. It is important, however, to remember that the health officer like the poet is born rather than made. We greatly need the right type of man but we do not need the wrong type; and THE NATION'S HEALTH plans to discuss with some frankness the question of the personality of the health officer during the next few months.

The first point to be remembered is that the health officer is an administrator, and an administrator of a peculiarly complex and exacting service. The scope of public health work is changing rapidly and the very first task of the officer is to choose wisely between conflicting demands for his attention and to balance judiciously the claims of old and new lines of endeavor. He must formulate for his own community, and in the light of local conditions and local psychology, a program which shall attain a maximum of results in life saving for the sum of money at his disposal. To do this requires a balanced judgment which education can develop but can not create.

When a sound health program is once formulated the next problem of the executive is to choose his staff with discrimination, to adjust their relative responsibilities and to give them the free hand that develops personality while keeping the machine as a whole in smooth and harmonious working order. He must understand the problems of the humblest inspector and be able to foster and stimulate that psychological approach by which even a minor official who comes in daily contact with the public accomplishes results without friction and builds up an atmosphere of public approval for the department which he represents. The health officer must comprehend something of the principles and practice of public

The Health Officer's Personality

health nursing and must be prepared to solve the complex claims of generalized and specialized service, instructive and bedside care, as applied to his own community. He must know how clinics should be organized so as to operate with efficiency while preserving an atmosphere of personal sympathy free from the deadly taint of institutionalism. He must understand the problems of the laboratory worker and the statistician. He must often assume responsibility for the administration of an isolation hospital and sometimes for the organization of a system of refuse disposal. Let the reader compare in his own mind the relative simplicity of the problems which must be solved by any other municipal department head in the whole range of city administration and he will realize how unique are the demands made upon the health officer.

It is obvious that a sound knowledge of the principles of public health science is essential to success in this difficult field and it is clear that theoretical instruction must be supplemented by a generous assignment of practical field work. Such training as is given in our best schools of public health will be of inestimable value in preparing the way for effective health administration. Yet such instruction will be wasted upon a student who does not possess that combination of broad vision and human sympathy and moral courage which makes for leadership.

THE Public Health Service for administrative purposes, has divided the Continental United States into seven Districts and placed a regional director in charge of each. The headquarters

of these seven districts are as follows: New York City, N. Y.; Chicago, Ill.; Denver, Col.; San Francisco, Calif.; Seattle, Wash.; New Orleans, La.; Baltimore, Md.

U. S. P. H. S. District Organization

This is a forward step in a very necessary decentralization, incident to the expansion of the service.

The quarantine functions of the service are police functions under very definite and detailed regulations, and the medical officer in charge of a quarantine station has little need for further instructions. Problems rarely arise which necessitate invoking a higher authority or making extraneous contacts.

The hospitals of the service are operated under a code of regulations equally definite and in such detail, that most questions can be decided by the officer in charge.

The sanitary police functions and hospital functions in themselves could be discharged without decentralization, but the burden on Washington, even in these functions, can be lessened by having district offices.

The service, in the newer conception of its duties and obligations as a national health service, has expanded far beyond sanitary police or quarantine duty and the administration of hospitals. It no longer simply operates quarantines and hospitals under police power and regulations sufficient within themselves, but today participates in the solution of all problems which affect the health of the nation.

In solving these problems police power has little part, their solution depends upon voluntary co-operation and the hearty support of all agencies, official and unofficial, interested in health.

Public health has expanded from the prevention of contagious disease to the prevention of all disease. It has gone further—from the negative prevention of disease to the positive idea of sound bodily health. With this expansion the National Public Health Service must keep pace and must go even further, showing leadership in health problems of national scope.

These district directors will serve as a point of contact with official and unofficial health agencies and with the general public, obviating the necessity of directing all health business through the neck of the bottle—Washington.

The directors of districts will not only serve to make a local point of contact for extra service agencies interested in health, but will be able to secure better coordination between the various service units themselves, quarantine, immigration, hospital—epidemic or research—within the area.

The district idea of decentralization has wonderful possibilities in providing the machinery for the coordination of official and unofficial or voluntary health effort with each other and with the National Public Health Service in nation-wide programs against disease.

JUST as the sanitarians of the world were beginning to think that yellow fever was an almost extinct disease, there came in March last, rumors that it had appeared in epidemic form in

Bucaramanga, Colombia.

There had been no reports of the disease elsewhere in Colombia; the seaports of Colombia and Venezuela were believed to be free of yellow

fever; the only cases in the Western Hemi-

Yellow Fever in Colombia

sphere where it was known to exist were Bahia, Brazil, and Tampico and Ciudad Victoria, Mexico; Bucaramanga was far in the interior of Colombia, many days travel from the seacoast; at an altitude of three thousand feet, an altitude not usually conducive to the spread of yellow fever; granted that the disease was yellow fever, it was a mystery how it could have penetrated to such a remote locality without leaving an epidemic trail behind it.

The Colombia government decided that the disease was not yellow fever; there were rumors that epidemic pneumonia had appeared among the laborers brought from the mountains for the completion of the railroad which is to connect Bucaramanga with Puerto Wilches on the Magdalena River; returning travelers told tales of an epidemic of black-water fever; the epidemic continued.

Finally on April 28 a commission acting under the aegis of the International Health Board left Colon for the scene of the epidemic. The chairman of this body was Assistant Surgeon General J. H. White, U. S. P. H. S.; the other members were Dr. O. L. Pothier of New Orleans, La., and Dr. Wenceslao Pareja, of Guayaquil, Ecuador. Since all of these physicians are recognized yellow fever experts any decision at which they might arrive as to the identity of the epidemic at Bucaramanga would be final as to its being or not being yellow fever. They took with them cultures of the *Leptospira* of yellow fever and Weil's disease in order that serological tests might be made. By mid-May the commission had confirmed the disease as yellow fever, had secured an appropriation of thirty thousand dollars from the Colombian government to combat the disease, and had established a four day quarantine at Tamboa, one day out from Bucaramanga, to prevent the extension of the disease into new territory. The diagnosis was made clinically and by the Pfeiffer cross reaction, and it was on the latter evidence that the Faculty of Medicine at Bogota (the capital of Colombia) was convinced of the absolute accuracy of the diagnosis. This test was also made with positive results on two active and two past cases, one moderate and one severe case in each group, both the Mexico and Guayaquil *Leptospira icteroides* strains being used. The accuracy of the diagnosis cannot be gainsaid.

Bucaramanga is three days from Puerto Wilches, which is the point of departure from the Magdalena River. It has a population of about 25,000 and is situated at an altitude of 3,000 feet; it is surrounded by the towns of Rio Negro, at 15,000 feet elevation, about 20 miles away, with 15,000 inhabitants; Florida Blanca, at 1,500 feet,

seven miles away, with a population of 5,000; and Giron, with 5,000 inhabitants, five miles away. The last three named towns are connected with Bucaramanga by good automobile roads. This is believed to be the third time that Bucaramanga has had yellow fever, and the last time it lasted two or three years.

It is thought that the disease entered Bucaramanga from Cucata, an uneradicated residual yellow fever focus for the past fifty years. Cucata is five days travel away to the north, and is situated at an altitude of 900 feet, close to the Venezuelan border. It has a population of 30,000, with about seventy thousand people around it, and it is a large trading center. Of the five days journey from Cucata to Bucaramanga, three days are over a *paramo* or plateau having an elevation of 10,000 feet, and it is thought that the disease was carried to Bucaramanga in this way. An infected person gets out to the edge of the *Paramo*—that is one day's journey—and infects the mosquitoes there; somebody from that point contracts the disease and is able to travel across the *paramo*—that is three days—and infect the mosquitoes on the other side; subsequently someone gets the disease at that point and carries it into Bucaramanga—one day's travel away.

The question arises as to whether or not Puerto Wilches (the port of Bucaramanga on the Magdalena River) is also infected. It is not thought to be infected now but it is believed that the disease has been there but has burned itself out. Has the disease spread down the river? This is not now known but those who have studied the situation locally are inclined to believe that it has not. Has the disease spread up the river? Probably it has spread to Berrios, where it is thought there are still a few cases, and perhaps to Medellin which is the end of the railroad which runs from Puerto Berrios.

The chief quarantine officer of the Panama Canal, Surgeon W. C. Rucker, U. S. P. H. S., on May 28, 1923, issued the following order for the protection of the Canal Zone:

On account of an outbreak of yellow fever at Bucaramanga, Colombia, quarantine against passengers not immune to yellow fever and from all Magdalena River ports above Barranquilla to complete six days from port of departure, is hereby imposed.

Boarding officers will take temperature of all non-immune passengers arriving from North Colombia ports, and those having fever will be placed in quarantine to complete six days from port of departure. Certification of ships' surgeons as to daily temperature of passengers en voyage will be accepted. The local addresses will be taken of all non-immune passengers landing and they will be required to report once daily to complete six days from port of departure to a quarantine officer to have their temperatures taken. Failure to so report will result in arrest and detention at the quarantine station.

Dr. White has returned to the United States and will direct the eradication campaign from Washington, D. C. All local operations will be directed by Dr. Frederick A. Miller of the International Health Board. Doctors Pothier and Pareja have proceeded to Cucuta via Curacao, D. W. I., and the Lake Maracaibo region of Venezuela. It is hoped and believed that the intensive measures which Dr. White has put in force will rapidly stamp out the epidemic and thus yellow fever will be still further driven into oblivion.

THE modern pessimist reading the numerous appeals for the handicapped adds one more count to his indictment of modern progress and concludes, sincerely no doubt, that the evils of society are on the increase. We are all, optimists and pessimists alike, prone to make such conclusions unless we view conditions in the perspective of time. We see the evils of the day and, without comparing with the past, conclude that the world grows worse.

It often happens that a new insight or an awakened conscience causes us to take up a problem which was no less a problem before, but which was left untouched. During the last five years we have learned much and done much about the salvaging of the human scrap heap. More data are at hand to show the distressful conditions of the handicapped. Knowing now about the evils, superficial observers and pessimists draw false conclusions. The conditions are probably no worse than they were; we are merely better informed. That which should be ground for optimism, namely, that we had been roused to action on an old problem, is used to prove the opposite. Yet here is the most hopeful social program that has been devised. It is not entirely new in theory, but almost entirely new in general social application. Medical and health agencies have been rehabilitating physically as a matter of course for many years, but only within the last five years has the social program of physical and vocational rehabilitation been coordinated for the remaking of men physically, economically, and socially.

The progress of this work as disclosed by the reports of the Federal Board for Vocational Education should encourage all believers in social progress. Nearly all of the states have joined in this cooperative enterprise with the Federal Government. Many thousand handicapped people are training the faculties which are left to them. Workmen's compensation commissions, education

departments, and medical men are cooperating to restore the injured workers to self support. The fact that large numbers of handicapped people are being discovered, does not mean that there are more than formerly; it means merely that the facts of our true condition is being discovered by our good efforts to cure one of the sorest spots on the social body.

It is to be hoped that this forward movement will be continued. The present provision for federal cooperation expires next year. The movement will go forward but haltingly if Federal support and stimulus are withdrawn.

ONE of the most important of the many valuable services rendered by the American Public Health Association has been the formulation of standard laboratory methods for the carrying out of various public health examinations. In one sense any standard procedure is abhorrent to science since "it is characteristic of science and progress that they continually open new fields to our vision."

Standard methods must necessarily be subject to repeated revision; but, on the other hand, for official administrative purposes it is absolutely essential to have some agreement among analysts in order that the results obtained in different places and by different observers may be reasonably comparable. The standard methods for the examination of water and sewage of the American Public Health Association have given us since 1905 an ideal compromise in the shape of authoritative procedure subject to change every few years to meet the advancing developments of science. During the present year the fifth edition of *Standard Methods for the Examination of Water and Sewage* and the fourth edition of *Standard Methods of Milk Analysis*¹ have both been issued and as before these documents will be found invaluable to every laboratory worker.

From the bacteriological standpoint the fifth edition of "Standard Methods" differs from the fourth (1920) in two important respects: the phenolphthalein method of titrating media is definitely abandoned in favor of the new and more exact phenol red adjustment; and the litmus lactose agar plate is abandoned in favor of the eosin-methylene blue agar medium, which is now recommended as the alternative to the Endo agar for the confirmation of *Bacterium coli*. The new

1. Both to be obtained from the American Public Health Association, 370 Seventh Ave., New York City.

milk standards differ little from those of the fourth edition except in establishing a ratio of 1-4 instead of 1-5 for the relation between the official plate method and the direct microscopic count and in the inclusion of methylene blue reduction test as a provisional method for detecting milk of poor quality.

It is exceedingly probable that important advances will be made and new changes indicated during the next few years. The use of various inhibitive dyes furnishes real promise of the possibility of a better presumptive test for *Bacterium coli* than has ever been devised in the past,² and it seems likely that in the future greater official recognition will be given to the distinction between *Bacterium coli* and *Bacterium aërogenes*.³ The new standard methods, however, represent the best knowledge of the time and they should be strictly followed by all who are engaged in the practical sanitary control of water and milk supplies.

THE report of the Chicago Department of Health for the years 1919, 1920 and 1921 is full of interest for the sanitarian. The material is presented in an exceptionally clear and com-

The Chicago Health Department

compact form, with a summary of results accomplished and recommendations for the future under each major division of health department activities.

The expenditures of the department for various functional activities are fully tabulated and it appears that the total appropriation for the department was increased from approximately \$.29 per capita in 1911 to \$.53 in 1921. Of the latter sum, less than \$.07 is spent for sanitation and the promotion of cleanliness and approximately \$.42 for the direct conservation of health. An unusually large place is occupied by the educational work of the department including an account of the health and sanitation exposition of 1920 and the pageant of progress of 1921. Under the general head of publicity and education is to be found an account of the eight weeks course in home nursing which in the opinion of competent experts has done more harm than good, by flooding the community with inadequately trained women some of whom pass as nurses and collect the fees which should be paid only to those of adequate training and experience.

2. C. E. A. Winslow and A. F. Dolloff: The Relative Effect of Certain Triphenylmethane Dyes Upon the Growth of Bacilli of the Colon Group in Lactose Broth and Lactose Bile. *Jour. of Infect. Dis.*, 1922, XXXI, 302.
3. M. Levine: Bacteria Fermenting Lactose and Their Significance in Water Analysis. *Iowa State College of Agriculture and Mechanic Arts Official Publication*, 1923, xx, No. 31, Bulletin 62.

The report of Dr. Herman Spaulding makes an urgent plea for the immunization of the preschool child against diphtheria and shows gratifying progress in the immunization of contacts, nearly 16,000 such persons having been immunized in 1921. With an increase in cases and carriers during the past three years the death rate has been kept at a low level. Smallpox, as in so many cities of the United States, is on the increase, but all the other acute communicable diseases show a satisfactory trend. It is interesting to note that fumigation was abandoned in favor of terminal disinfection in 1920. A very interesting new step was the creation in November, 1919, of a division of mental hygiene and neurology under the Department of Health. Special attention is also devoted to the problem of venereal disease control and Health Commissioner Robertson makes a vigorous plea for a more extended and systematic campaign along this line. Unusually aggressive investigations are reported as having been made to determine the prevalence of venereal disease in lodging houses and among the unemployed, among prostitutes, and among men admitted to penal institutions.

The report of Mr. Charles B. Ball, chief of the Bureau of Sanitation is of particular interest on account of a long and effective plea for the adoption of a comprehensive zoning plan. It is distinctly encouraging to see the health officials of a large city realizing the responsibilities in regard to such broader problems of community sanitation.

THIS is the season of the year to emphasize once more the possible dividends in health and comfort to be obtained by the artificial cooling of occupied buildings. We take it for granted

Why Not Keep Cool?

that we should keep our houses warm in winter and then accept the heat of summer as a dispensation of divine providence. Yet it is just as easy, though somewhat more costly, to cool a room in summer as to warm it in winter. The results of some years' experience in the Blackstone Hotel in Chicago, the banking offices of Kuhn, Loeb & Co., in New York, and the Mount Sinai Hospital in the same city¹ have demonstrated the feasibility of this procedure and it may be hoped that those who are suffering from high temperatures this August will give serious consideration to the possibilities of securing protection against such conditions in the future.

The Beccari System of Organic Waste Disposal

ITALY and, to some extent, European countries in general have long used the open manure pit and prized it as a most important adjunct to agriculture. The nitrogen loss from such a process of open fermentation is from 6 to 14 per cent and may rise even to 64 per cent if there is no protection from rain water. Dr. Guiseppe Beccari developed a closed fermentation cell with the idea of conserving the fertilizing value of manure. It was then found that garbage,

and eight by nine in plan. The walls are of brick, plastered with concrete on the inner sides. Around the interior of the cells are four horizontal baffles about two inches wide and spaced about two feet apart. In each corner of the cell is a vertical air passage having an opening into the cell at the lower side of each of the horizontal baffles. Three of these vertical ducts are open at the upper end. The fourth one is closed and above it is an opening in the roof of the cell. Cells

in the cell. In the bottom of the cell is slotted false bottom which serves to admit air drawn from openings in the outer walls and through which liquids are drained to a sump located underground; the overflow from the sump being connected with a sewer.

In operation the cell is charged with garbage through a trap door in the roof. Air enters through the ports below the false bottom circulates through the mass slowly, being retarded by the horizontal baffles on the wall. If the cell has been in operation for a little time, and the charge is seeded with liquid from the sump, in less than a week fermentation will be well under way and the temperature of the fermenting mass will rapidly rise to approximately 145 degrees Fahrenheit. The volatile products of the fermentation (nitrogen and ammonia) pass into the turret above the cell and liquid products drain back into the cell. At the end of thirty-five days the content of the cell is removed through a door in the side of the cell. The garbage is found to have been converted into a nearly dry inoffensive humus, dark brown in color, with practically no odor and, according to Italian investigators, with a high fertilizing value. Dr. Vittorio Racah, of Florence, in writing on this subject says, "numerous analysis of diversified samples of fertilizer (from Beccari plants located in Florence, Carrara, Pistoia, etc.) show that the average analysis of sweepings digested in Beccari cells is about as follows:

View of the 208 cell Beccari plant at Florence, Italy, showing units of cells with storage shed in the background

weeds, dead animals, and practically any kind of organic material could be fermented with success in such a closed cell. This discovery led to the construction in many cities of municipal disposal plants based on the Beccari principles of fermentation.

Six municipal plants were in operation in Italian cities in May, 1922, the largest of these being a 208 cell installation at Florence. At this same date one other plant was nearing completion and five cities including Naples had contracted for Beccari plants for the disposal of the city waste. Garbage disposal plans for Naples include three plants with a total of eight hundred cells. Rome, Milan, Messina, several other large cities and many small ones were negotiating for disposal plants. The Beccari system of garbage disposal is being introduced into the United States by the American Beccari Corporation of New York.

The construction and operation of the system can be made clear by a brief description of one of the cells. Such a cell is about ten feet in height

are usually built in groups of four so that when the four openings through the roof are located in the center of the group one tower is constructed over the four openings. In the tower are four horizontal shelves covered with layers of absorbent earth and sulphate of iron which function in fixing the volatile products resulting from the fermentation of the material

Approach to an Italian plant by which the garbage is hauled directly to the roof of the cells and dumped through the trap-doors in the top of the cells.

Nitrogen consists of 8 parts per M. phosphoric anhydrides 3.7 parts per M, while ordinary agricultural open manure pits, even the most modern and perfect, rarely produce a product containing more than 4.5 parts of nitrogen per M., and of phosphoric anhydrides 2.5 parts per M, according to analyses contained in agricultural treatises on the subject."

It must be remembered that in relation to garbage, these figures cannot be taken at their actual values for they represent the results obtained from street sweeping. They do, however show the conservation effected by fermentation in a Beccari cell. In view of the difference in conditions in Italy and the United States and the general skepticism with which American sanitarians are apt to look on any claims of financial returns from disposal works it is only fair to state that the officials of the American Beccari Corporation minimize the use of the humus as a fertilizer. 11 conditions in this country prove to be such that this angle of the disposal becomes profitable, well and good, but the backers of the Beccari process urge their fermentation process on the grounds of simplicity, efficiency and economy.

The cells are simple in construc-

tion; after filling no care is required until the process of fermentation is completed; the product is well digested, free from odor, practically, sterile, can be dumped without creating a nuisance. There are no odors around the plant, and the cost of upkeep is slight.

A four-cell experimental plant is now in operation at Paterson, N. J. Naturally, some doubts were felt as to the success that could be attained with such a fermentation process in a climate differing considerable from that of Italy. The Paterson experimental cells were put to a severe test by being put in operation during the winter season. Located in an open wind-swept field they produced, during the winter months, a satisfactory product in a period approximating forty days, which indicates that the winters of the United States extended by somewhat less than a week the period required for digestion in the warmer climate of Italy.

Early in March of the present year a representative of THE NATION'S HEALTH visited the plant at Paterson. The day before this inspection one of the cells had been emptied and the humus spread on the ground nearby. Several inches of snow fell during the night and at the time of

inspection it was necessary to dig through this snow which had covered the humus for more than twelve hours. The humus was found to answer the description of the Italian investigators? It was dark brown in color, nearly dry, as inoffensive to handle as ordinary garden dirt and, a few inches below the surface, still warm in spite of the covering of snow. The cell from which the humus was removed had been charged with several whole hams and chickens. Search for remains of these revealed only clean bones and on breaking these the marrow was found dried to such a stage that it could be easily powdered with the fingers. In spite of the objection of the Italian that supervised the construction of these cells, they were charged with the typical garbage of the American city. The charge contained an occasional tin can, some paper, and wood shavings from the sweepings of slaughter house floors. Apparently this inorganic matter in not too excessive amounts has no influence on the progress of the fermentation process.

Practically no odor could be detected on the roof of the cells even with the doors of the turret open, and the odor in the interior of a partially di-

Graph showing the development of microbiological phenomena in Beccari zymothermic cells, taken from a biological study of the subject by Prof. Gustavo Gasperini, Director of the Florence Board of Hygiene.

gested cell was not extremely objectionable.

Visual inspection of the product produced by Beccari zymothermic cells created a very favorable impression. The desirable thing, of course, is to have a fair sized plant constructed in some city that a careful study of its operation can be made extending over a period of a year or more and using garbage of a composition typical of that collected in the municipalities of the United States. The experiments so far carried on a small plant during the winter months give no indication that any insurmountable difficulties would be encountered. Actual construction cost and annual operating expenses will be of great interest when they become available. It seems hard to conceive how they could even equal those of a reduction plant, as the fermentation cells are simple in construction; no machinery is required; the cost of upkeep will be limited to repairs; and the cost of operation is practically limited to the labor for charging and emptying. No attention is required throughout the thirty-five or forty day period fermentation.

What actually happens during the fermentation is not completely understood. Whereas the cells do produce a good product practically the only investigation of the way in which this is accomplished was conducted by Prof. Gustavo Gasperini, director of the Florence Board of Hygiene. The results shown in the accompanying graph were obtained in this study of the fermentation of sweeping from the paved streets of Florence. The bacteriological studies of the content of four cells show that as soon as the process begins actively the gelatin liquifying organisms decrease so that by the sixth or seventh day cultures made with dilutions equal to the original samples produce far less liquification.

"While the fluidizing colonies are on the decrease, colonies of thermophilous micro-organisms begin to make their appearance in the cultures in agar, which latter micro-organisms, which were almost entirely absent on

the first and second day, attain to their maximum development when the liquifying colonies have fallen to a minimum and the temperature rises to about 70 degrees Centigrade." Among the thermophilous micro-organisms Prof. Gasperini found some predominating species not previously described. To these are given the names *Bacillus thermophilous mucoramosus* and *Bacillus thermophilous trichovaginitus*. The species of the complementary microflora are, for the most part, chromogenic. One of the latter, described by Gasperini as "very singular" has been named *Bacillus polymorphotestaceus*.

Generally speaking, *B. coli* disappeared about the tenth day, but if samples were taken near the walls where the material was kept moist by the liquid trickling down the walls positive samples may be obtained under a condition such as this even after

mometer registered 59 degrees Centigrade and none of the animals inoculated died. After this the other two baskets were removed and the tassels subjected to cultural tests, but no colonies of anthrax could be found on agar.

Layers of moist fecal matter from cess-pools were placed in cells. Transformation in such matter proceeded more slowly probably because to their lesser permeability by air. *Ascaris lumbricoides* are destroyed by the process of fermentation and the embryos of *Ankylostomum duodenale*. Wherever ova of nemathelminthes were present in the fresh soil no trace of them could be detected after the third week.

These above are the finding of Prof. Gasperini. They indicate that from a sanitary and hygienic point of view the process of Beccari fermentation is satisfactory. It may be wondered what applicability there is in this country of the findings relative to the disposal of moist fecal matter. Small installations are recommended for camps and country estates. These may be used for the disposal of night soil, garbage, and other organic material.

The American Beccari Corpora-

Design by the American Beccari Corporation for a Beccari organic waste disposal plant for a city of 30,000 inhabitants.

three weeks or a month have elapsed.

Tests were also carried out with anthrax spores. Linen tassels soaked in cultures enriched with spores were placed in baskets containing self registering thermometers. These baskets were then packed with some of the same refuse that was used in charging the cell. Four of these baskets were buried in the charge at a depth of one half meter; one in the center of the cell and the others at varying distances from the wall. At the end of the eighth day the first basket was removed. The thermometer recorded 52 degrees Centigrade. The anthrax infected tassel was shaken in sterile water until the water became turbid and this liquid inoculated into two guinea pigs. One of these died on the third day and one on the fourth. Blood examinations showed anthrax to have been the cause of death. On the twenty-first day another basket was removed; the ther-

more estimates that one cell will care for the garbage of approximately one thousand population. An illustration shows the proposed design for a thirty-two cell plant, sufficient for a city of thirty thousand. The cells are arranged in two rows through the center of the plant. The ventilating turrets are arranged along the sides leaving a clear driveway through the center of the plant. By means of entrance and exit ramps the collection trucks along the top of the cells dumping the garbage through the trap-doors in the top of the cells. Along both sides of the cells are storage sheds where the humus is removed.

The reports from Italy and the preliminary experiments at Paterson promise well. What its actual applicability will be in the United States can only be told when some city ventures the construction of a fair size plant and operates it for a reasonable length of time.

Nineteenth Annual Meeting National Tuberculosis Association*

Not Natural Causes Only, But Purposeful Effort Must Be Credited With the Continuous Fall in the Death Rates From Tuberculosis

LOOKING back at the nineteenth annual meeting of the National Tuberculosis Association, recently closed at Santa Barbara, among the impressions which stand out most clearly are first of all, the determination of all those present to make the tuberculosis movement a bigger factor in the improvement of public health than ever before, conserving and forwarding the gains already made; secondly, a recognition clearly emphasized in a number of different ways that the conscious work of the national, state, and local tuberculosis associations has been productive of results in life saving and would, and could be productive of greater results in the future. The delightful setting of Santa Barbara, the splendid hospitality of our California hosts, and the good fellowship of those in attendance at the meeting, are among other impressions that will last for a long time.

It would take more than the space allowed for an ordinary article to attempt to recount all of the interesting features of the programs of the various sections. The most that can be done in this brief space is to tell of a few of the interesting features.

Dr. Lawrason Brown's presidential address struck a sympathetic cord when he reminded us that one of the greatest needs of the campaign against tuberculosis, is more extensive research for the purpose of securing a positive cure for the disease. "The long search and the scantiness of financial reward have discouraged many brilliant scientists from entering the tuberculosis field. A complete eradication of tuberculosis must follow along one of two lines. First, by vaccination or by some other method of treatment which is as successful as the administering of quinin in malaria must be discovered. Another possibility is that pulmonary tuberculosis like leprosy and typhus will gradually recede until in countries with a high hygienic civilization it will be of slight importance. At the

present time public education in disease prevention, increased sanatorium facilities, and adequate after care in order to prevent a relapse, are the best available means of still further reducing the mortality and case rates."

Prevention that Prevents

In the report of the executive office read by Dr. Linsly R. Williams, managing director, and more particularly in the first session of the sociological section, abundant evidence was presented to show not only that the death rate from tuberculosis has declined in a remarkable way during the last twenty years, but also that the reasons for the decline are to be found primarily in the work of the anti-tuberculosis campaign. To Dr. Louis I. Dublin belongs the credit for correctly demonstrating that the anti-tuberculosis campaign may justly say that it has accelerated the decline in the death rate. Dr. Dublin clearly pointed out that the constitutional school of thinkers are represented by Raymond Pearl, are not basing their conclusions on sound hypotheses when they say that the decline in the death rate is due to perfectly normal causes, entirely beyond control of ordinary human activities. Dr. Dublin clearly pointed out that the educational, institutional, case-finding, and general campaign for building resistance and preventing infection had contributed in no small measure to the cut in the death rate. Dr. Williams and Dr. Haven Emerson also pointed out that the recent studies of Dr. Charles Hendee Smith in one of the most congested districts of New York would seem to indicate that there is not only a decline in mortality and also in morbidity from tuberculosis, but a decline in infection as well. Dr. Smith's figures show that the evidence of infection in young children is very much less pronounced in the group which he studied than in the group studied in many large European cities.

In the clinical section much attention was given to methods of treatment that have been helpful in arresting tuberculous diseases. Artificial

pneumothorax was discussed directly or indirectly in eight or ten different papers. The evidence presented clearly indicated that this method of treatment is of proved value, not only in moderately advanced, but in relatively far advanced cases. Dr. W. D. Sansum, of the Santa Barbara Cottage Hospital, also contributed an interesting feature of the meeting when he pointed out that tuberculosis patients suffering with diabetes have been successfully treated by the use of insulin, coupled with the ordinary hygienic and dietetic treatment. The significance of Dr. Sansum's work will be found in a great many centers, particularly where there is a prevalence of diabetes in combination with tuberculosis.

The results of sanatorium treatment were also carefully scrutinized in several different ways, both in the American Sanatorium Association, which met the day before the opening of the National Association meeting proper, and in the Clinical and sociological sections. There seemed to be a certain difference of opinion as to the possible value of the sanatorium. Some of those present felt that the sanatorium's biggest work can be accomplished when used as an educational institution. Others, expressed a sharply opposed feeling that its chief function is to keep patients until well or restored to working efficiency. Dr. Dublin made an interesting contribution in this respect, when he pointed out that the actual saving of lives brought about by sanatorium treatment during the last fifteen years, which had in many instances doubled the expectancy of life by tuberculosis patients, had registered a very decided effect upon the reduction in tuberculosis mortality. The follow-up of sanatorium patients was also a subject of considerable discussion. The Association adopted a formal resolution for a continuation of the follow-up study made by Miss Whitney, statistician, begun about two years ago. In general the sanatorium, in spite of the criticism levied against it, seemed to come out of the discussion with its usefulness clearly

*We are indebted to Philip P. Jacobs, Ph.D., publicity director, National Tuberculosis Association, for the data contained in the above comment.

indicated and with its field of activity considerably enlarged.

Among the nurses present at the meeting, who were very well represented, the keenest discussion was aroused on the subject of training of pupil nurses. Miss Grace Holmes, of Portland, Ore., startled those present by pointing out that less than 10 per cent of the pupil nurses of this country who are graduating every year, get any knowledge at all of the care of the tuberculosis patients during their two or three years of training.

It is impossible to carry on this discussion of the several interesting features of the program in more detail. To say that the meeting was interesting and that the program was well planned and that the sessions were all enthusiastically attended, is stating in somewhat commonplace terms what are the real facts.

As to the business of the conference, the following directors were elected at the opening session:

Representative Directors.—Dr. John W. Flinn, Arizona; Dr. W. Jarvis Barlow, California; Dr. Ethan Allen Gray, Chicago; Dr. Stephen J. Maher, Connecticut; Dr. T. Z. Cason, Florida; Dr. William F. Smith, Idaho; Dr. F. E. Sampson, Iowa; Dr. A. T. McCormack, Kentucky; Dr. Martin F. Sloan, Maryland; Dr. J. H. Kellogg, Michigan; Dr. Henry Boswell, Mississippi; H. R. Cunningham, Montana; Mrs. John M. Fulton, Nevada; Dr. S. B. English, New Jersey; Dr. James Alex Miller, New York City; Dr. J. Grassick, North Dakota; Dr. R. H. Bishop, Jr., Ohio; Dr. Ray W. Matson, Oregon; Edward A. Wood, Pittsburgh; Rev. F. W. Gregg, South Carolina; Dr. Herbert Acuff, Tennessee; James H. Wallis, Utah; Dr. E. J. Rogers, Vermont; Dr. C. H. Barksdale, West Virginia; Dr. J. D. Shingle, Wyoming; and Dr. LeRoy Peters, New Mexico.

Directors at Large.—Wallace S. Allen, Connecticut; William G. Irwin, Indiana; Mrs. F. E. Whitley, Iowa; Henry S. Dennison, Massachusetts; Gertrude Vaile, Colorado; Homer Folks, New York; Lilla C. Wheeler, New York; Fred M. Stein, New York; Theodore S. Huntington, Ohio; Sherman C. Kingsley, Pennsylvania; Mathew Woll, Illinois; Dr. John H. Peck, Iowa; Dr. Ralph C. Matson, Oregon; Dr. Hoyt E. Dearholt, Wisconsin; Dr. W. Jarvis Barlow, California; Dr. A. M. Forster, Colorado; Dr. David R. Lyman, Connecticut; Dr. Max Biesenthal, Illinois; Dr. James A. Britton, Illinois; Dr. William DeKleine, Michigan; Dr. Lawra Brown, New York; Dr. Charles Stover, New York; Dr. A. C. Bachmeyer, Ohio; Dr. Robinson Bosworth, Minnesota; Dr. Paul A. Lewis, New Jersey.

The following officers of the Association were elected by the Board:

President: Dr. Livingston Farrand, president Cornell University; **Vice-presidents:** Dr. W. Jarvis Barlow, Los Angeles; and, Dr. Chas. J. Hatfield,

Philadelphia; **Honorary vice-presidents:** Hon. Warren G. Harding, and Col. George E. Bushnell; **Secretary:** Dr. George M. Kober, Washington, D. C.; **Treasurer:** Mr. Henry B. Platt, New York; **Executive Committee:** Dr. Jas. Alexander Miller, New York; Dr. David R. Lyman, Wallingford, Conn.; Dr. J. W. Pettit, Ottawa, Ill.; Dr. C. C. Browning, Los Angeles; Dr. A. M. Forster, Colorado Springs; and Mr. John A. Kingsbury, New York.

Conference of Secretaries

The National Conference of Tuberculosis Secretaries, which had existed for several years as an auxiliary of the Tuberculosis Association was reorganized and its membership limited to executive secretaries of state and local tuberculosis associations and heads of service of the National Tuberculosis Association. An executive committee of seven, consisting of

three state, three local, and one national representatives was elected. The committee is comprised of the following: Dr. Robert G. Paterson, Columbus, Ohio, Mrs. Sadie Orr-Dunbar, Portland, Ore., Mr. A. M. De-wees, Philadelphia, Pa., Mr. Hugo Brown, Buffalo, N. Y., Miss Sidney Maguire, Los Angeles, and Mr. Frederick D. Hopkins, of the National Tuberculosis Association.

This committee elected the following officers: Dr. Paterson, president; Miss Meyers, vice-president; and Mrs. Dunbar, secretary and treasurer.

Memphis was selected as the next place of meeting, the meeting to be held during the latter part of April, or early part of May, 1924. Section chairmen will be selected in the near future by the new executive committee.

CALIFORNIA HEALTH PROGRESS

The Twenty-seventh Biennial Report of the State Board of Health of California which covers the period from July 1, 1920 to June 30, 1922 contains encouraging reports of progress along many health lines. Smallpox, however, shows a steady increase in California and the problem of rat and squirrel plague continues to be serious. The experts who are dealing with the latter problem now recommend that efforts should be concentrated on the destruction of the squirrels in the immediate neighborhood of the towns, villages, and rural habitations rather than to attempt a more widespread eradication over wide areas. Rabies has also been on the increase in California during recent years.

On the other hand, the typhoid

death rate has shown a gratifying reduction well illustrated in the chart which is reproduced herewith. Infant mortality rates are astoundingly low. For the six large coast cities (San Francisco, Los Angeles, Oakland, Portland, Seattle, and Spokane) the infant mortality rates for the six years 1916-1921 have in no single year and for no single city been as high as 80. In 1921 three of these cities San Francisco, Portland, and Seattle had rates below 50.

Among special problems which have received particular attention from the California Board of Health there may be mentioned the sanitation of automobile camp grounds, fair grounds, and roadside camps, for all of which excellent sanitary regulations are in force.

Meeting of the American Medical Association—1923

The Obligation of the Physician to Translate and Transfer the Sciences Into Everyday Health for the Masses Is Clearly Felt

TRENDS and tendencies can be seen and traced in professions as in human growth, or in the incidence of disease, even if opinions are not susceptible of statistical expression.

There can be no question that the spirit of the modern physician as presented for his fellows and exhibited to his patients is shown in these annual gatherings, even if those who attend number but 6 per cent of the enrolled membership of the organized doctors of the land, and but 3.5 per cent of the registered practitioners of medicine.

This is the public forum where the physician, whether delegated to express the policy determined upon by his county and state society, or offering the results of his own personal studies and experience to the critical discussion of his fellow practitioners, speaks, as it were, in public and takes the consequences.

What were the policies proposed, what the action of the officers and delegates, what did science or its application gain from the San Francisco meeting of the American Medical Association?

Expression Made on Cancer

The session may be said to have opened with the Sunday evening public meeting on cancer, where the president and the president-elect recorded their belief in the efficacy of education of the public and their testimony as to the constant progress of science in simplifying the essentials of self-protection. The veteran campaigner, Dr. Bloodgood, capitalized all his hard won experience as a clinician in arousing the interest and directing the determination of the audience to take warning in time and use the skill of the surgeon with courage. It was hardly to be doubted that San Francisco would welcome such direct authoritative teaching if for no other reason than that this city with its cancer death rate of 162 per 100,000 in 1922 takes the leadership of the country (U. S. rate is 90) and is followed closely by Sacramento and Los Angeles in this unusual eminence.

Monday, June 25, gave the first opportunity to judge of the subjects and programs which the House of Delegates would be called upon to consider, and in some measure their attitude expressed in the discussions raised by the reports of officers and the presentation of resolutions.

Dr. W. A. Pusey, president-elect of the American Medical Association. Dr. Pusey graduated from the New York University Medical College in 1888, and has been practicing in Chicago since 1892. He is professor emeritus of the Department of Dermatology of the University of Illinois.

Dr. De Schweinitz in his address reiterated the well considered policies of the Association in matters of education, paying particular attention to the standards to be required for acknowledged specialists in the clinical branches and urging still ampler facilities throughout the country for the reeducation or continuation of training of physicians whose work keeps them usually apart from centers of medical teaching.

The chief topics of Dr. Wilbur's address were the need of long distance policies for the future and the necessity of promoting medical examinations of healthy persons as a safeguard against most of the preventable

defects and diseases. He spoke from a point of vantage rarely reached by the president drawn immediately from medical practice. He was looking upon the American Medical Association from without, from the academic heights and with the perspective of those who guide international health undertakings. He spoke with the apt and homely allusions of the experienced family practitioner, with the wise simplicity of the consultant. Before the House of Delegates and again at the opening meeting of the Association, Dr. Wilbur made clear the call on the one hand for high standards and broad scope in the training of physicians and on the other their obligation to translate and transfer the sciences into the daily lives of their patients, both the well and the sick.

"The attitude of the medical profession used to be," he said, "Don't come to the doctor unless you are sick. The object of modern medicine is to take the normal man and serve as a shield to protect his body from the diseases that would attack it. . . . Modern medicine tends more and more to emphasize the preventive rather than the curative."

Dr. Wilbur stated that "the opportunity before the organization was almost beyond parallel, and that it was in possession of a knowledge that if applied to the fullest extent to human need and human development it would afford untold happiness to humanity." He went on to say:

Our growing youth need instruction in health matters. They need not only to know life for their own protection, but to protect the lives that will depend upon them as they grow to maturity. Our greatest service to the human race can be done only when we help to make possible a marked increase in positive health. Already our efforts are crowned with a marked prolongation of life, particularly through the economic productive period. We can free human beings from many of the things that bring them down before the race is run. As a race our success is dependent upon the strong and the reproduction of the strong. In the control of the human

germ plasm lies man's future. In this great field we have not as yet even reached the amateur stage.

We hear much of the melting pot and of Americanization, but how many of our citizens realize that good minds and sound bodies can come only from those with these qualifications. Since all who come to our shores are permanently added to our American stock, to see that we are protected against the diseased, the feeble-minded and the criminal, we need to keep out the diseased as well as the diseases. Great possibilities are before us. When we can keep the Spirochaete of syphilis out of the body of every newborn babe we shall have added enough to human life and happiness to heal the wounds of the great war.

Reports of Councils

The Bureau of Legal Medicine and Legislation reported upon its first year of work which has been largely devoted to pressing the reasonable demands of the medical profession for consideration in the operation of the laws restricting the use of narcotics and alcohol. It seems likely that requests for issuance of whisky, bottled in bond in packages of such size as will permit dispensing without breaking bulk, direct to patients on physicians' prescriptions, will be met by favorable action by the prohibition commissioner.

Efforts have been made to obtain from Washington the courtesy of notice to the medical profession prior to any contemplated change in regulations.

Again the plea made at the Boston meeting in 1921 is vigorously endorsed, namely the request that the annual registry tax under the Harrison Anti Narcotic Law be reduced from \$3.00 to \$1.00 as it was before the war.

Perhaps the most constructive activity of this new Bureau has been the preparation of a bill which would require all those applying to state licensing boards for the privilege of treating the sick by any method or school, to have passed examinations in the basic medical sciences, such examinations to be held by a non medical board. Such a bill has been proposed and was defeated by the non-medical cults in Maine, Minnesota and Wisconsin. Ultimately the public will have to protect itself against fraud and incompetence of service to the sick in some such way as is proposed by the American Medical Association.

The Secretary's report emphasized the growing leadership of county Medical Societies in operating diagnostic clinics, providing post graduate instruction for their members, organ-

izing free clinics for the indigent, running health columns in the daily papers, and affiliating with other agencies for improvement of public health.

Health Instruction

During the year the chief accomplishments of the Council on Health and Public Instruction have been the launching of *Hygeia* under the leadership of Dr. Victor C. Vaughan, the chairman of the council and editor-in-chief of the journal.

The completion of the model state anti-narcotic law as authorized in 1921 permits the turning over of this part of the Council's work to the Bureau of Legal Medicine and Legislation. This text was made the basis of a new law passed in New York state and signed by the Governor. The general support of the other professions and of the trades concerned, for this model law makes its extended adoption probable.

The recent publication of standard procedure and forms for a complete history and medical examination of healthy persons fulfills the obligation imposed by the House of Delegates last year.

The Council on Medical Education and Hospitals rendered an admirable report.

Briefly, they advise more freedom in the use of hours required within major groups of instruction in the standard curriculum. They find the situation as to the medical schools and of students satisfactory, with 17,700 students enrolled, the largest number since 1912, of whom 90 per cent have the higher educational qualifications, while but 6.2 per cent were so prepared in 1904. They are convinced that there is no shortage of doctors and will be none as far as one can see ahead. There is now one M.D. to every 724 of our population. They believe that the relative lack of physicians in some rural areas can best be met by a guarantee of \$2,500 to \$3,000 a year to the physician from the community concerned. They call attention to the New Hampshire law permitting a town to pay for a physician from tax money if one can not be obtained otherwise. The telephone, the automobile and the great increase in use of hospitals have radically altered the distribution of physicians. The Council estimate that between 80 and 90 per cent of all sickness can be adequately cared for by competent general practitioners and that 90 per cent of the sick can be well cared for in their homes. It is obvious, however, from the extent of hospitaliza-

tion that the laity think otherwise and are constantly increasing their demands for hospital care, especially for maternity cases.

There are found to be 3,671 internships in 654 approved hospitals with 187,314 beds (one intern for 51 beds) and 3,944 dispensaries serving eight million persons annually. Abuse of medical charity is believed to be held down to a reasonable minimum. A good word is said of some of the group clinics which are found to maintain high standards both in the treatment of patients and ethically in relation to the profession.

The report of the subcommittee on nursing was endorsed, its recommendations quoted, and a committee called for, representing the medical and nursing professions and the laity, to agree upon a standard nursing curriculum and a classification of nursing training schools according to the quality of their educational work. Dr. William Darrach, of New York, Dr. Winford Smith of Baltimore, and Dr. Thomas McCrae of Philadelphia, are to be the medical members of such a joint committee.

The House of Delegates took important action on a number of matters of considerable interest to the public and the medical profession. They passed a resolution condemning the present commercial distribution of lye in packages for household use and called for national restrictions to prevent the blindness and damage to the throat, etc., which occurs commonly from ignorance of the nature of lye. They approved of participation by the American Medical Association in health exhibits when these are initiated or approved by the local county or state Medical Society. This will perhaps bring to a close the commercial activities of at least one group of promoters who have succeeded in exploiting both the public and the medical profession to their own profit.

They passed a resolution approving of a campaign of education of physicians by the American Medical Association in the methods and results of periodic medical examinations of apparently healthy persons, this to be carried out through state and county societies and through hospitals and medical schools. Unless something of this kind is done the public, now eagerly following the advice of the national health agencies to have such annual examinations, will find the medical profession largely unprepared.

They approved of a declaration

that "No need now exists for the entrance of the American Red Cross into the field work of public health activities or into community clinic work."

A committee was approved to continue conference with President Harding and his representatives relative to plans for the formation of a national welfare department in the Presidential Cabinet.

The request of the U. S. Veterans' Bureau to be accorded official representation in the deliberations of the American Medical Association was quite properly denied, as would be a similar request from the Pension Office.

The only controversial matter before the House was settled in an entirely suitable manner. The policy of the Bureau of Legal Medicine and Legislation in attempting to correct the tendency of existing regulations of the Prohibition Commissioner and to secure the purity of such liquor as is dispensed on physicians' prescriptions, was clearly endorsed. Other resolutions designed to endorse private groups of physicians in legal action, to demand unlimited usage of alcoholic liquor by patients on physicians' prescriptions, etc., upon the presumption that a majority vote of the medical profession has established alcohol as a necessary and valuable therapeutic agent, were properly tabled.

It would be a task worthy of the excellent work of the Council on Pharmacy and of the entire resources of the American Medical Association to make a scientific study, clinical as well as laboratory, of the therapeutic action and effect of alcohol in disease. Until this is done the American Medical Association should make no more official statements which can be interpreted as giving comfort to one or other of the groups seeking nowadays to make political capital out of what is essentially a scientific and social problem worthy of our best educational and research efforts.

Chicago is to be the next meeting place, and Dr. William H. Pusey of Chicago the next president.

Mortality Improvement Among Insured Negro Population

The colored people have finally awakened to the importance of the health problem, says Dr. Louis I. Dublin, in *Opportunity*, April, 1923. They have actually determined to profit from the opportunity to reduce the unnecessary loss of life from which they have suffered.

These conclusions are based upon the very extensive experience of the Metropolitan Life Insurance Company among colored people during the last decade and more. At the present time, there are insured in the Industrial Department of this company over one million eight hundred thousand colored persons. These include both males and females of all ages from the beginning of the second year of life, engaged in every conceivable occupation and distributed over virtually every state of the Union. For the most part, these colored policy holders reside in the towns and cities of the country. The experience is really an urban one; yet, the number of these colored policy holders is so very large that we may well expect them to reflect the actual mortality conditions that prevail among all the colored people of the United States.

The Metropolitan experience is available in great detail for the year 1911 and for every year thereafter up to and including 1922. In these twelve years, the mortality of the colored policy holders declined from a rate of 17.5 to 13.6 per 1,000, which represents a drop of 22 per cent, or more than one-fifth. A very gratifying improvement, even if not quite so marked, occurred among the colored people living in the registration states of the United States, among whom the mortality rate declined 12.5 per cent between 1910 and 1920. In New York City proper, the decline among the colored people was actually 24.3 per cent. These improvements when translated in terms of longevity mean that colored males insured in the Metropolitan have in the short interval of about ten years increased their life span by nearly six years and colored females by nearly five years. It must be remembered that the public health movement among Negroes is only of very recent origin and the full effect of the work will not be felt for years to come.

In 1911 tuberculosis was responsible for 418 deaths for each one hundred thousand colored persons insured in the Metropolitan. In 1922 that rate was 244, or 42 per cent less. During the last ten years the typhoid rate among the colored declined 75.8 per cent. The decline

in malarial fever was almost identical with that for typhoid fever. The mortality for children under 15 years of age has improved 47.5 per cent.

Cancer shows an increase of 19 per cent; diabetes, 79.7 per cent; cerebral hemorrhage, 28.1 per cent; and organic diseases of the heart, 6 per cent. "These four conditions combined account for 27 per cent of the total mortality of colored policy holders, and it is therefore, discouraging to find that such important conditions are not on the mend but are actually getting worse."

There has been a very marked increase in the mortality from syphilis during the period of this experience. In 1922 the death rate from syphilis, locomotor ataxia, and general paralysis of the insane was 42.9 per 100,000. This is more than double the rate of 1911. It may well be that some of the increase is the result of franker and better reporting of these diseases by physicians,

but it is to be doubted if this is sufficient to explain the increase of 110 per cent, especially when during the same period, the syphilis rate for the whites declined from 9.6 to 9.5. The fact still remains that the rate for colored persons is close to five times as high as for whites.

"Both white and colored people can profit from more frequent physical examination and from following the advice and instruction of skilled physicians in the mode of life which is called for where serious impairments are found."

The New York State Y. M. C. A. has created a new department of physical education in connection with its work, Archie J. Stearns, formerly in charge of the health and recreation department of the Bronx Union Y. M. C. A., will assume its direction August 15.

Conference of American Federation for the Hard of Hearing

THE hard of hearing constitute a neglected group. The health officer concerns himself with communicable disease in its early stages, but collects no data regarding the resulting handicaps in individual cases; incipient deafness goes unrecognized in its curable stages; retarded children, lacking but one sense, are continually being classified as of low mentality; residual hearing is not capitalized in special methods of training to overcome character defects which are ultimately the chief penalty of deafness; and for the child who becomes deafened at the age of seven or eight years, after his training as a hearing individual is well under way, is, to all practical effect in reaching the great mass of the afflicted, educational opportunity is lacking in this country.

The Annual Conference of the American Federation of Organizations for the Hard of Hearing, which met in Chicago, June 18 to 20, dealt with the educational problems of the hard of hearing, with social measures to ameliorate their condition of isolation, with deafness as an industrial handicap, and especially with the psychology of the deaf. Dr. Max A. Goldstein was particularly drastic in his criticism of methods of education which had any objective other than to train the deafened person, to place dependence upon any mechanical aid to the detriment of lip reading, for here, as in other groups, self-reliance grows with free and easy communication and whatever tends to isolation serves as a mental handicap. Deafened children, therefore, are subjects for special training to overcome barriers to communication, and are to be classified on the basis of residual hearing. Lip reading is essential for all persons who cannot hear a whisper at a distance of six or eight feet, and speech is to be developed or conserved in every case. The deaf child requires the consideration of the community, but so far his best hope has been in the direction of voluntary agencies, a hope which is the better grounded under present co-operative effort between the Society of Progressive Oral Advocates, the national societies of teachers for the deaf, and the American Federation of Organizations for the Hard of Hearing.

Dr. James Kerr Love, of Glasgow, Scotland, received the hearing due to the man who first originated lip reading classes for adult deaf persons and whose intelligent appreciation of deafness as a handicap has resulted in his classical advice to mothers of deaf children and in general acceptance that sense education of the deaf must begin earlier than the school age for normal children. Dr. Love spoke of the impossibility of classifying the "queer hearing" of the deaf as one-half, one-third, or one-fourth efficient. From the standpoint of the deafened, classification is better made on the basis of residual hearing than upon etiology of the condition. Medical inspection in schools should assure the radical treatment of all cases requiring special attention to the nose and throat. Infectious cases should be followed until cleared up. School medical service may even be considered inadequate until it can mean even hospital treatment where that means cure or prevention of the condition of deafness from the clinical side. Educationally, the deaf require special treatment. Every large city requires special classes for all affected children. Rural communities should consolidate for such work.

Interesting questions are involved in the cost of such special education, especially in the cost of training the backward deaf, a group in which perhaps 15 per cent requires eight or nine years of special training. Is it worth it? Whatever the decision, the adult deaf must never be discouraged in the effort to attain means of getting on with other people.

On the subject of tests, Dr. Love declared for the use of the human voice, for the educability of a deaf person and the method employed depend upon the degree of auditory sense useful in general communication. Residual hearing, of course, should be utilized to the utmost in training and in speech conservation.

Many interesting communications were made on the psychology of deafness. Social work to break down their isolation was discussed in the paper of Earle E. Eubank, and a particularly hopeful prospect of release from this handicap was offered through psychiatric methods by Dr. Earl A. Menninger, and "deliberate

deafness," through mental acceptance of the limitations of the handicap was the message of Dr. Gordon Berry.

Dr. Harry E. Mock reported on the highly constructive rehabilitation service effectual in Chicago for these handicapped. The final test of service to this group is to find the way and means to give them a place in commercial and social activities. This is in a fair way to constructive effort through industrial surveys, vocational studies and vocational training, and coordination of all agencies.

Sewage Disposal Situation in Philadelphia

By an ordinance approved July, 1907, the Philadelphia Department of Public Works was authorized to investigate and report upon a plan of sewage disposal to meet the requirements of the local situation. It was not until August, 1915, that the State Commissioner of Health approved the city's plan. The city was instructed to have in operation before July 1, 1917, the facilities involved in the first stage of the plan for collection and treatment of sewage in the Frankford Creek section.

Land has been purchased for two of the three proposed sewage treatment plants and the collecting sewers involved in the first stage of the plan have been completed according to statements appearing in *Citizen's Business*, February 8, 1923, published by the Bureau of Municipal Research. The initial units of the northeast works are still incomplete. Among other reasons causing this delay were the unusual conditions existing during and immediately following the world war.

Under date of December 13, 1921, in a letter to the mayor and council, the State Commissioner of Health urged the expediting of construction work and called attention to the greatly increased pollution of the Delaware river. This very polite warning from the Commissioner prompted the city to order "full speed ahead" on the northeast works.

The city is now worried over a decision of the city solicitor that the unappropriated balance of the estimated cost (\$29,075,000) should be considered an encumbrance on the city's borrowing capacity.

First International Health Education Conference

Health Formerly "Happened" to the Lucky Ones; Through the Adaption of Definite Curricula It Now Becomes An Educational Objective

THE First International Health Education Conference was held at San Francisco, June 28 to July 6, as a section of the World Conference on Education. This Health Conference was called in the name of four great national groups: the American Medical Association, the National Education Association, the American School Hygiene Association, and the American Child Health Association.

As the American Medical Association and the National Education Association convened in San Francisco at the same time, it was possible to secure as speakers the foremost physicians, educators, and public health leaders. Such authorities in medicine and science were represented as Dr. E. V. McCollum, Dr. Alonzo E. Taylor, Dr. Haven Emerson, Dr. William Palmer Lucas, Dr. Thomas D. Wood, Dr. Guy S. Milberry, Prof. C. E. Turner, and Dr. Bird Baldwin.

Internationality Assured

The international character of the conference is assured by the fact that official delegates came from twenty-four countries, including India, Indo China, Italy, Japan, Mexico, New Zealand, Norway, Peru, Scotland, Denmark, France, Hawaii, Spain, Switzerland, Turkey, Uruguay, Belgium, Canada, Chile, China, Costa Rica, Czecho, Armenia, and Poland.

From America such varied professional groups were represented on the program as the National Committee for Mental Hygiene, the League of Red Cross Societies, American Social Hygiene Association, National Health Council, American Home Economics Association, American Physical Education Association, American Playgrounds and Recreation Association, National Y. W. C. A., National Women's Christian Temperance Union, National Tuberculosis Association, Girl Scouts of America, and Boy Scouts of America.

Two main problems were discussed at the Conference—the health education of the child in the school and training the student in teacher-training centers to teach health. Every angle of these two problems were covered by leaders in pedagogy; nutri-

tion, physical education, home economics, school nursing, school medical and dental work, and school administration.

It is only five years ago that the Child Health Organization of America, now the Health Education Division of the American Child Health Association, launched a nation-wide campaign to interest teachers in the training of children in the practice of health habits. The public first became aware of this movement through weighing and measuring contests, health poster contests, health play, hot school lunches, mid-morning milk, and monthly weighing and measuring. These activities were usually initiated and administered by groups outside of the school and were later taken over by the school authorities.

Health-Habit Teaching

Then parents and physicians began to hear of the fine health-habit teaching of an individual teacher or perhaps of a whole school staff. The next step was the placing of health teaching on the school curriculum through the work of a special department, such as that of physical education, domestic science, or science.

Then health education came into its own in some of the foremost school systems of America. Courses of study in health were developed which called upon every subject in the curriculum to make its contribution for arousing and maintaining the child's vivid interest in the fulness of living which is both the means and goal of health.

Into these courses of study has gone the brilliant originality of hundreds of classroom teachers, in the footsteps of whose experimental work the rank and file may safely follow.

And, not content to stop with the child in the school, groups outside the school are carrying creative methods of health education into every type of after-school activity for children of school age, and into recreational work for young men and women.

Out of this First International Conference there will come who knows what further vision, what wider practice?

Iowa Legislation Proposes Sanitary Code for Hotels

A whole code of new sanitary regulations for Iowa hotels and restaurants is proposed in bills introduced in the lower house of the Iowa legislature by Representative Yenter. Under these measures hotels would be required to provide 96-inch bed sheets, could not force patrons to sleep on straw mattresses, could not have quilts on the beds, could not use cracked dishes in the dining rooms, and would be forced to provide at least 400 cubic feet of air space for each person sleeping in its bedrooms. Cooks would be prohibited from smoking in restaurant kitchens, diseased persons could not be permitted to work there, uncovered pies would be barred, and cats could not be allowed inside.

Closing in on Yellow Fever

"Definite progress was made during 1922 in the International Health Board's campaign to drive yellow fever from the world," says President George E. Vincent. "The comparatively small number of reported cases of the disease were confined to Mexico, to a restricted area in northern Brazil, to points on the West Coast of Africa, or to ships en route from one of these countries. The Mexican authorities warmly welcomed and supported the co-operation of the Board. To one familiar with the history of yellow fever, the fact that for a whole year Central America, the West Indies, and all but one country of South America were free from the scourge which for nearly two centuries ravaged these regions, is strikingly significant. It is hard to realize that this latest phase of the fight on yellow fever began only five years ago . . . It is too early to predict a complete victory, but the successors of General Gorgas share his faith that it will in time be won."

The people of this country spend \$500,000,000 a year on drugs in addition to other large sums for other means of obtaining relief from suffering and sickness.

Advance in Health Safeguards for Working Children

Twenty-two states now require the physical examination of every child applying for an employment certificate, according to the newly revised edition of a bulletin on "Physical Standards for Working Children," issued by the U. S. Department of Labor through the Children's Bureau. The bulletin contains the recommendations of a committee of physicians who were appointed by the Bureau to prepare a standard form for use in examination of children seeking to enter employment.

Since the publication of the first edition of the bulletin, two years ago, a considerable number of changes have been made in the various state laws with reference to such examinations, and the summary of legal provisions which it contains has now been brought up to date. One state, Virginia, is said to have advanced in this respect to a stage beyond that of other states, in that it now requires the examination of every working child at regular intervals during the years when he is especially susceptible to the strains of industry. It should thus be possible to determine whether the work at which he is engaged is injuring his health or interfering with his normal development. In certain other states a child must be re-examined when he goes from one employer to another, but since he may remain with his first employer until he passes the certificate age, the bulletin points out that this is not so adequate a provision as the new Virginia law.

In addition to the twenty-two states requiring a physical examination for every child before an employment certificate is first granted, eight others and the District of Columbia allow the certificate-issuing officer to require an

examination when he is in doubt as to the child's physical fitness, but many officers, it is said, do not realize the importance of this phase of their work. In eighteen states there is still no legal provision of any kind for physical examination of the child worker in these states, even when the child first enters employment.

involved the rise of another: caisson disease (known among the men as "the bends," and among physicians as "air-embolism") is concomitant with the use of compressed air. Among the 600 men who were employed in sinking the foundations for the St. Louis Bridge some years ago, there were 119 serious cases of caisson disease, fourteen of which were fatal. In building the original Brooklyn Bridge 110 men were similarly affected and three of them died.

According to the survey in *The Travelers Standard*, the great progress of New York City in combating the disease has been brought about largely by enactment of special laws for protecting the caisson workers. Only a few states have laws governing work in compressed air, and New York, New Jersey, and Pennsylvania are the only ones having legislative measures that definitely regulate the hours of labor and specify the hygienic conditions under which caisson work is permissible.

Persons working in air under abnormally high pressure may contract caisson disease in consequence of remaining exposed to the compressed air for too long a time, or of being subjected to a change in pressure that is too rapid to allow the human machinery to adjust itself. In order to avoid injurious effects, the change in pressure must be made gradually by means of what are known as "air-

locks," chambers which may be put in communication either with the interior of the caisson or with the outside air.

Every applicant should receive a careful medical examination before being employed, and these examinations should be repeated at least as often as once every three months. It is essential for every man to have normal lungs and kidneys and a good heart, and a high blood pressure should disqualify the applicant.

Expenditures of the Rockefeller Foundation

THE Rockefeller Foundation was chartered by special act of the New York State Legislature on May 14, 1913. The following statement of contributions and programs during the first decade of its existence is made by Edwin R. Embree, the Secretary.

While its chartered purpose is broadly stated as "the well-being of mankind throughout the

world," the work of the Foundation has become chiefly centered upon public health and medical education.

The expenditures during the first decade, 1913 through 1922, have amounted to seventy-six and three quarters millions (\$76,757,040), roughly divided as follows:

Public health	\$18,188,838
Medical education	24,716,859
War relief	22,298,541
All other philanthropic work	10,445,628
Administration	1,107,174

Methods of Combating Caisson Disease

The United States Bureau of Mines calls attention to the fact that through the use of compressed air there has been a remarkable reduction, in recent years, in the dangers and discomforts to which workmen are exposed while engaged in underground work. Unfortunately, however, the elimination of one evil has

The Occupational Progress of Women

An interpretation of census statistics of women in gainful occupations is the basis of a report by Mary Anderson of the Women's Bureau, Department of Labor, just issued. The most striking change taking place in the employment of women during the last decade seems to have been in the decrease in the numbers working in or for the home and in personal-service occupations, and a corresponding increase in clerical and allied occupations, in teaching, and in nursing. Significant changes took place as well in manufacturing and mechanical industries. Increases of more than ten thousand women were found among semi-skilled operatives in food, iron and steel, and clothing industries, in silk and knitting mills; in electrical supply, shoe, and cigar and tobacco factories; among laborers in cotton mills; and among forewomen and overseers in manufacturing plants. Operatives in automobile factories showed an increase of 1,408 per cent in women workers; the entire iron and steel industry, 145.4 per cent. All occupations studied showed an interesting situation of disproportionate increase of women as compared to the increase in the number of men employed in the industries. Women in public service increased 60.6 per cent, and in certain professions the number of women was trebled.

More and more industrial opportunities are being offered to women. It is easier to explain the increased number of women employed in given occupations than it is to find the reason for the variations in increase of employment of men in the same industries. In twelve occupations studied the percentage of increase for women was more than one hundred points higher than that shown for men in the same occupation. No one is surprised that men decreased in number while women increased as clerks in stores, as school teachers, as trained nurses, and as stenographers and typists; but why should men actors and showmen decrease 1,475 during this decade and women in the same profession increase 1,254? Why did the number of men authors, editors, and reporters decline 382 in ten years and women increase 2,497 during the same period. It is even less explicable to learn that male cooks increased 12,853 and general servants 11,292, when the reductions in these two classes among women runs into the hundreds of thousands.

Interesting health angles attach to

these shifts of occupation. Industrial working conditions are man-made and it remains to be seen what far reaching effects the almost universal entrance of women into the trades will have upon public health. There are in addition the considerations which arise in hazardous occupations. Many of the positions which women have entered during the last decade are necessarily classed as skilled trades, but involve the peculiar occupational hazards of diseases caused by metal dust and fillings, chemical, or other specific dangers.

Universal Gas Mask Has Been Developed

Development of a "Universal gas mask" which is considered to have the widest application of any gas mask thus far devised, and which fills every demand that may reasonably be made on a gas mask, was recently announced by the Department of the Interior as the result of experimental work performed by the Bureau of Mines at its Pittsburgh, Pa., station. The Department also announces the development of a "Fireman's canister" which is similar to the "Universal canister," but is smaller and lighter, thus making it more convenient for the use of city firemen. The Army gas mask gives no protection against ammonia gas used in refrigerating plants, or against carbon monoxid, a constituent of blast-furnace gas, producer gas, water gas, and coal gas.

To combine efficiently in one canister the absorbents for all noxious gases is difficult because the absorbents for certain gases are best when moist, whereas an absorbent or catalyst for carbon monoxid can be used only when perfectly dry. Hence it becomes necessary to use dry absorbents for the other gases.

After an extended series of experiments by the Bureau of Mines the "Universal" gas mask was developed. The canister contains granular absorbents, consisting of activated charcoal, for removing organic vapors; a filter of cotton wool for removing smokes, dusts, and mists; caustic soda fused on pumice stone for removing acid gases; another cotton-wool filter; fused calcium chlorid for extracting water vapor that inhibits action of the next absorbent; "hopealite," a mixture of oxids of manganese and copper with sometime silver and cobalt that destroys carbon monoxid; and finally silica gel for absorbing ammonia. The complete mask and harness weigh about 8.5 pounds. The "Fireman's

canister" weighs about 5.5 pounds and is more convenient to wear than the "Universal" mask.

The Universal and the fireman's gas masks may be worn in air containing small quantities of any noxious gas. An abundance of air is necessary, because the gas mask does not furnish the wearer with any of the oxygen necessary for life. An atmosphere in which a safety-lamp flame goes out must never be entered by a man wearing a gas mask. Oxygen breathing apparatus or air helmets only can be used in such places. Because of the danger from using an exhausted canister, a limit of six hours' use is put upon the universal and four hours' on the fireman's canisters.

In cool or cold weather the canisters should be worn under a coat because when warm they are more active against carbon monoxid than when they are cold.

Details regarding these gas masks are given in Technical Paper 300, by S. H. Katz, J. J. Bloomfield, and A. C. Fieldner, copies of which may be obtained from the Bureau of Mines, Washington, D. C.

British Empire Cancer Campaign

A new concerted movement called the British Empire Cancer Campaign, governed and directed by an executive council whose members will serve as chairman of working committees, each directed against some separate aspect of the cancer problem, has been organized. Medicine, surgery, human pathology, chemistry, physics, radiology, animal and plant pathology, hygiene, and vital statistics will all be represented. Individuals and institutions now working on the problem will be encouraged and helped financially where necessary. Discovery in any one branch will promptly be made known to all.

Correction

The report of the extent and cost of care of chronic disabled heart patients in the hospitals, dispensaries, and convalescent homes in New York City, prepared by Haven Emerson, chairman of the executive committee of the Association for the Prevention and Relief of Heart Disease, Inc., and published in the June issue of *THE NATION'S HEALTH*, was based upon material collected by Miss M. L. Woughter, executive secretary of the organization. The article should have been printed as a joint contribution from Dr. Emerson and Miss Woughter.

Contract Medical Service in Lumbering

We are indebted to Dr. L. J. Stauffer for the following description of the divided medical contract under which the Rose Lake Lumber Company of Rose Lake, Idaho, provides medical services for its employees.

The medical work of the saw mill and planing mill, both of which are in Rose Lake is handled by a resident physician at Rose Lake. The logging operations are carried on in the woods at points about thirty miles up the Coeur d'Alene River. This part of the medical work can be handled better from Coeur d'Alene and is carried on by the Coeur d'Alene Hospital Association of Coeur d'Alene, Idaho.

There are about two hundred employees in the village of Rose Lake when the mill is running two shifts of eight hours each. The medical work is handled on the contract system. One dollar is deducted from each employee's wages each month to which the company adds 50 per cent on its own account. For a period of less than one month a deduction of ten cents per day is made. This provides for medical, surgical, and hospital attention; accident and illness included, that is, illness not existing at the time the employee went to work for the company.

By law the medical services rendered are at all times under the supervision of the Idaho Industrial Accident Board.

The physician is furnished with a combined residence and office which is located near the plant. The hospital service, when necessary, is rendered by hospitals in neighboring towns, Kellogg being twenty miles east and Harrison twenty miles west, and with exceptional train service in both directions.

The medical service provided does not cover the families of the employees.

Disinfection of Tableware in Public Establishments

Drs. L. H. Dejust and Wilbaux Dardel of Paris have been carrying on extensive research in the subject of pathogenic bacteria on table utensils and the method of disinfection. Dr. Dejust has shown that the drying of dishes with a towel is not to be recommended, since, as a rule, the same towel is used to dry a large number of dishes before it is discarded. There results an enrichment of bacteria, which, after twenty or more operations, renders the towel capable of

contaminating sterile objects with which it comes in contact.

Toward the use of concentrated solutions of strong acids, Dr. Dejust is almost equally opposed, as the action of the acids on metal is dele-

rious. The sole solution of the problem seems to be in the use of boiling water. Glassware may be easily replaced with receptacles sterilizable by heat—metal cups or vessels of faience and porcelain.

Public Health Nursing Exhibit

Because there has been a constantly increasing desire on the part of the public to procure a real understanding of public health nursing a new poster series of twelve cards has been published by the National Organization for Public Health Nursing. This series describes by means of photographs and explanatory text the various phases of this profession. The cards are buff color and are nine by twelve inches in dimensions; they treat such topics as Child Welfare, Tuberculosis Nursing,

Industrial Nursing, Rural Nursing, Nursing in the city tenement, and School Nursing. Particular stress is laid on the fact that the Public Health Nurse is one of the teachers of community health and perforce must act as interpreter of health laws in terms of everyday hygiene.

The series is known as "Public Health Nursing Exhibit" and may be purchased by schools or others interested from the National Organization for Public Health Nursing, 370 Seventh Avenue, New York, N. Y.

Bathtubs Not Always Considered a Necessity

When bathtubs were first installed in the United States in the forties, they were attacked through the papers as extravagant and undemocratic, and were denounced by the doctors as a menace to health. As usual, governmental aid was sought and special taxes and licenses restricted their use. In 1843 Virginia put a tax of thirty dollars a year on bathtubs, and in 1845 a Boston municipal ordinance made such bathing unlawful except on medical advice.—*Science Service.*

Summary of Water Waste in Large Cities

The May issue of *The American City* presents a summarization of reports of surveys on water waste in many cities which is highly illuminative. In some cities the wastage runs as high as 21 per cent of the total output. In every case the results more than justified the cost of the survey which was counted a "profitable expense."

Outline of Progress in Hygiene

There is now available a history of the activities and organization of the Bureau of Labor Statistics of the U. S. Department of Labor. The volume, compiled by Gustavus A. Weber,

member of the staff of the Institute for Government Research, and published as Bulletin No. 319 of the department of labor, is a valuable brochure and the chronological list of publications presented under Appendix C practically constitutes an outline history of progress in industrial hygiene.

New and Effective Method of Cleaning Sewers

Apparatus in the form of a self-propelling nozzle for cleaning sewers has been devised. The machine, described in the current issue of *The American City* is a simple, easily operated tool which travels from the manhole to the obstructing roots or sticks under its own power and it is claimed that upon reaching the obstruction the revolving blade cuts away the matted mass of roots or sticks up to an inch in diameter. The water which revolves the root cutter washes away the loosened fibers, roots, and sticks, and gives the obstructed point a good cleaning.

Large Sum for Public Protection

The *American City* reports on the basis of a survey conducted by S. W. Straus & Co., New York City, that ninety-two cities plan to expend in 1923 more than \$260,000,000 for schools, police, fire, and various other administration buildings. More than a

score of other appropriations pending will bring the total for 120 cities to \$350,000,000. This is exclusive of the sums to be expended in these same cities by the Federal government.

Messenger Boys Enlist for Drill

Western Union messenger boys in New York City have been organized into a military unit and are being drilled by regular army officers. The Western Union company proposes by this method to command better service, concomitant with the increased physical strength and mental alertness of the boys.

The first drills began several weeks ago at the main building, where the boys go after their day's work and learn how to march, drill, and exercise. The work is a combination of army and Boy Scout methods. In addition to the military drill, which is expected to improve their bearing on the street, the boys are taught that their uniform is worth taking care of, that cleanliness is next to godliness, and that no regular soldier smokes on duty.

Lest these attractions fail to make the proper appeal the Western Union will establish a summer camp this year, at which every boy will have two weeks' vacation. If the plan is successful it will be extended to every city where there are a large number of Western Union employees.

Architecturally pleasing is the children's unit of the Detroit Municipal Tuberculosis Sanatorium. Its capacity is one hundred beds. The unit has been in active use since its completion in the summer of 1922.

LATE HEALTH DECISIONS IN THE COURTS

By DOROTHY KETCHAM, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Industrial Commission is without power to make the payment of compensation payable on the applicant's submission to an operation for hernia pursuant to a stipulation agreed on by the insurer and the majority of the Commission. The findings must state whether or not the injury received is compensable under the statute or the reasonable rules adopted by the Commission and applicable to such cases, making its award accordingly.—*Broton v. Industrial Commission*, 210 Pac. 982.

THE Supreme Judicial Court of Massachusetts, May 19, 1922, upheld the authority of the Board of Health to require the denaturing of "rot" or "spot" eggs. It was urged that the defendant was compelled to break eggs before selling them for manufacturing purposes, that the regulation destroyed a well known commercial product, and deprived the defendant of property without due process of law. It was undisputed that the eggs were decomposed spot and black rot eggs, unfit for food and no denaturant had been applied. The defendant company dealt in eggs in all stages of decay. The court states that a "regulative measure may require precautions to avoid possible danger, as well as to restrict conditions actually harmful."—*Commonwealth v. E. E. Wilson Co.*, 135 N.E. 376.

AN INJURY blinding a one-eyed employee was held compensable as a total "permanent loss" of both eyes by the Supreme Court of Illinois, June 21, 1922. In the opinion of the Court "it is now a well-established rule in this state and other states, that where an employee, who previous to his employment has lost an eye, loses the other eye as the result of an injury, or who has lost an arm, and loses a leg as a result of an injury arising out of and in the course of his employment, he is entitled to compensation for total permanent disability."—*Heaps v. Industrial Commission*, 135 N.E. 742.

APRIL 10, 1922 the Supreme Court of Pennsylvania decided that an injury occurring before the hours of service is compensable as one "arising out of and in the course of employment." The facts of the case are stated briefly: Peter Carlin was employed as a night watchman, his hours being from 6 p. m. to 7 a. m. About three o'clock in the afternoon of March 27, 1919, he went from his home to the colliery where he received his weekly wages; "afterwards, in the neighborhood of 5 o'clock, while walking to a shanty used in connection with his employment, he was caught and injured between a coal car and a breaker foundation. . . . Carlin died June 5, 1919. The fractured ribs were on the left side, but his death was due to an abscess on the right; though the wound on the left side healed, he was never well after he received the injury. The abscess was discovered about five or six weeks after the accident and he died a few days after it was located. The causal connection between the abscess and the injury to the left side was shown by medical evidence to such an extent that we could not say the board or the court below committed error in holding it sufficient on which to base a finding that deceased died as a result of injuries received in the cause of employment. The testimony deduced from the related facts gave rise to the medical conclusion that the abscess followed as a direct result of the injury."—*Carlin v. Cox Bros. & Co., Inc.* 117 A. 405.

THE Supreme Judicial Court of Washington, August 31, 1922, upheld the constitutionality of the labor department to declare any occupation to be extra-hazardous. The law provides that the department may, after hearing, on its own motion or on application of any person interested, declare any occupation to be extra-hazardous. The department in this case had power to declare the employees of a retail coal yard to be in an extra-hazardous occupation.—*State v. Bayles* 279 Pac. 20.

THE Supreme Judicial Court of Maine, October 4, 1922, held that in the following case the accident caused death by accelerating a previous disorder and is compensable. The employee in question was a blacksmith who came from the main shop at the company's mill to do horseshoeing and other work at different camps in the wood whenever his services were needed. While riding the employer's horse from his home near the mill to a nearby camp, the horse reared and bucked, threw the rider, dragging him a few feet. "Witnesses say that the horse in turning to make for the stable, stepped upon the prostrate man's back." Lachonee walked home, started out again on another horse and on arrival in camp reported the occurrence to the foreman. This day he worked. The next he did not, complaining of a pain in his leg and of heart trouble. The doctor's examination showed him to be "generally lame, bruised in the left leg, and with a special pain in his side." He returned to work for two or three weeks but the lameness increased. In February he was dismissed by the foreman as "all gone." Ultimately he died at the hospital April 3, 1921, the cause of his death being given as asystole.

The court held that the requirement of notice had been regarded and that although the heart disease was chronic "if Lachonee, but for the hurt, would not have died at the time at which, and in the way in which he did die, then, within the meaning of the Workmen's Act, the unfortunate occurrence, though it merely hastened a deep-seated disorder to destiny, must be held to have resulted in an injury causing death."—*Lachonee's Case*, 118 Atla. 370.

THE Supreme Court of Utah, November 24, 1922, passed upon the finding of the Industrial Commission that an accident accelerated the chronic disease of the heart from which the individual suffered and of which he died. The Court states that the finding of the Commission must be supported by some substantial testimony or "reasonable conclusions, legally deducible from facts proved." The physicians' statements as exemplified are, "that this condition was going to develop in Mr. Salisbury, no matter what he did. Now the accident may have precipitated it a little sooner, but as to say definitely whether it did or not I wouldn't be able to say that for sure."—*Chief Consol. Mining Co. v. Salisbury*, 210 Pac. 929.

SANITARY AND HYGIENIC ADVANCE

Causation of Industrial Accidents

H. M. Vernon in discussing the status of present knowledge regarding the causation of industrial accidents (*J. Indust. Hyg. Med.*, 1923, v. 1, p. 14) is led to conclude that fatigue may cause a moderate increase of accident frequency when the hours of work are long; that accidents are at a minimum at 67 degrees Fahrenheit; and that probably fatigue has very little to do with the considerable increase of accidents which is generally observed during the course of work spells. The rise is due chiefly to the psychical state of the workers.

This latter point is illustrated by the experience in a shell factory employing both day and night shifts. The accident rate of the day shift was at a maximum in the second spell of work and fell rapidly in the third, while the night shift accidents with one exception fell fairly steadily the whole night through. The day workers started work in the early morning when in a depressed condition, that they brightened up gradually especially after their tea and food at 9 a.m. and that they got into a more and more lively and careless state of mind as their dinner hour approached. The night shift workers, however, came to work in a lively and excited state, but gradually calmed down during the night as they had nothing to look forward to except an unexciting breakfast and bed.

Wholesale Killing of Rats in Hawaii

"Lives and fortunes are at stake in a tremendous war against field rats now being conducted by the territorial board of health and the sugar plantations of the Hawaiian Islands" (*Science*, lvi, 1459, Dec. 15, 1922). Aside from a damage to sugar cane in excess of one hundred thousand dollars a year, there is the ever present danger of bubonic plague. Twelve deaths have occurred during the last twelve months on the Hamakua coast.

The new method for the wholesale killing of rats, now being tried out on the Honakaa plantation, consists in spreading poison cakes broadcast

through more than ten thousand acres of cane fields and waste areas. This has resulted in such a reduction of the rat population that where the board of health previously trapped more than two thousand rats a month, it now catches only about fifty. The poison used is barium carbonate. This is mixed with flour dough and made into small round cakes and coated with paraffin, which protects them from dampness and molding.

A man on horseback, dropping a rat cake about every ten feet, can cover an area of thirty-five acres in a day, at a total cost of about sixteen cents per acre. This procedure, repeated two or three times a year is sufficient to control thoroughly this very serious pest.

Water-Borne Typhoid Outbreak

A severe tax on the capacity of a "lake" storing spring water for the supply of Cochrane, Ont., resulted in a depression of the water level three feet below that in a connecting lake which was badly polluted. The normal direction of flow was reversed and polluted water entered the town supply. The possibility of some such accident had previously been discussed by the municipality and a by-law passed providing for the expenditure of a considerable sum for further developments. Unfortunately the town did not proceed with that work nor with the purchase of a chlorin apparatus which was also recommended.

At the time of reporting by Dallyn (*Eng. News-Record*, April 19, 1923, 90, 16, p. 711) the outbreak had reached some 600 cases with twenty deaths. There were sixty emergency nurses in town and seven extra doctors attending to the sick.

Valuable Fuel Manufactured from Household Refuse

Sheffield (England) turns its rate payers' refuse into fuel and sells same for five dollars a ton. Two incinerators of the "top feed" type treat household refuse, after it has been handled by a screening plant and its various constituents separated so they can be economically utilized.

As shown by the screening process

the composition of household refuse is: Dust 33.3 per cent; fine cinder, 27.1 per cent; large cinder 18.5 per cent; debris, 14.37 per cent; tins, 1 per cent; tags, 0.4 per cent; paper 3.6 per cent; and vegetable matter 3.73 per cent.

The larger cinder forms a valuable fuel which is used for steam raising purposes at the corporation baths in the city. The results of the plant have been so satisfactory that new works are being constructed that have a capacity of 120 tons of briquettes a day, in addition to dealing with many tons of large cinders.

Organism of Bovine Tuberculosis Identified

Gordon and Brown identified the organism of bovine tuberculosis in ten out of thirty cases of tuberculosis in children under twelve years of age. Among the twenty-three cases under five years of age the organism was bovine in six instances; among the seven cases between five and sixteen years of age four were of bovine type. Of the twenty-two fatal cases, four were of bovine type. Twelve necropsies were performed. In all cases in which the point of origin was the alimentary tract the organism was bovine without exception. The human type of bacillus was recovered from all cases having a respiratory point of origin. (*Am. J. Dis. Child.*, March, 1923, xxv, 3, p. 234.)

Phthisis Mortality

The supplement to the 75th annual report of the Registrar General for England and Wales, Part IV, Mortality of Men in Certain Occupations, divides stone-mason class into those employed on sandstone, those employed on limestone, and those employed on granite. The comparative mortality for the sandstone workers was 415, for the limestone group 129, and for the granite group 127. (*Lancet*, March 3, 1923, 1, 5192, p. 453.)

Novel Bath Tub

An ingenious gypsy made a temporary infant's bath tub by arranging an automobile curtain in a soap box when the nurse could find no basin large enough for the purpose. (*P. H. Nurse*, Feb., 1923.)

A new ruling of the United States Bureau of Chemistry officially forbids the return of spoiled canned foods by distributors to the sources from which they were obtained, stating that the shippers of such foods will be liable to criminal prosecution.

Vaccination by Mouth Commands Attention

Considerable attention was devoted to the subject of vaccination by mouth in the discussions of the Health Committee of the League of Nations at Geneva. The Calmette vaccine against dysentery is being extensively administered in this way in Greece and in Russia, and favorable results have been obtained with vaccines against dysentery, cholera, and typhoid fever. The report of the Provisional Epidemic Commission of the Health Section of the League of Nations recognizes administration by mouth as an optional method of vaccinating against all these diseases.

Hydrogen Ion Concentrations and Flocc in Alum Solutions

In a study of the relation of pH to the formation of flocc in alum solutions Theriault and Clark (*Pub. Health. Rep., Feb. 2, 1923, xxxviii, 5, p. 181.*) have attempted to elucidate one of the many little-understood phases of water purification. The results are summarized as follows:

The hydrogen ion concentration of the final mixture of water and alum is of fundamental importance in the formation of the flocc. When other possible factors are left out of consideration, optimum conditions for flocc formation will be found within a narrow zone of pH centered for dilute solutions at pH 5.5. The more dilute the water in total salt content and the less the alum added, the narrower becomes the pH zone with which optimum flocc formation is to be found. Consequently, precise pH control should in favorable cases permit of great economy in alum dosage.

Effectiveness of Social Hygiene Literature

A report on the effectiveness of social hygiene literature (*J. Social Hyg., Feb., 1923, i, 2, p. 84*) closes with the following sentence:

It is interesting to note that fear seems to have little value as an incentive to the maintenance of high standards of conduct, but while not a positive incentive, it undoubtedly serves as a negative check, or inhibitor of various forms of sex expression. When causes of fear, such as harmful consequences are thought to be guarded against, or eliminated, the value of the fear incentive is largely lost; hence the best foundation for social-hygiene literature seems to be in arousing the mastery impulse, and in stirring desires for achievement, approval of self and others, and, in making right conduct or, at least, its not too distant consequences, attractive enough to hold attention and become a determiner of conduct.

Influence of Meat-eating Upon Comfort and Efficiency

A brief but highly suggestive contribution by Bassett, Holt, and Santos, from Cornell University Medical College, (*Am. Jour. Physiol., ix, p. 574*) indicates that the presence or absence of meat from the dietary for periods as long as one week has no demonstrable effect upon the power to perform physical work. On the other hand "there was a distinct and uniformly present sense of sleepiness for two or three hours during the afternoon period following the ingestion of 300 grams of meat."

Norwegian Illegitimacy Act Widely Discussed

The widely discussed Norwegian illegitimacy law, known as the Castberg Act, provides that the state become responsible for establishing the paternity of the child and for its maintenance. The mother reports to the local authorities and they must take action and see to it that the father support the mother and child (except in certain cases). The child must be supported according to the means of the better situated of the parents. Maintenance of the child is required until the sixteenth year and in some cases beyond that. If circumstances of wealth justify, the mother is required to contribute to the support of the child. The child inherits from the father's line as well as the mother's; but the property relations of husband and wife are changed to prevent any child that may be born out of wedlock from inheriting from either spouse, property which has come into the marriage through the other. In case of absconding or defaulting fathers the state cares for mother and child and there is no loss of citizenship attached to relief in such case. Where the paternity of a child cannot be determined, two or more males any of whom may possibly be the father of the child may be ordered to contribute to its support. Severe penalties are provided for any mother that may falsely accuse any male of being the father of her child.

Clarke discussed the working of this law with officials in Christiania and reports (*J. Soc. Hyg., March, 1923, ix, 3, p. 146*) that they are well satisfied with the results. Illegitimacy has not increased; the law has given no occasion for blackmail; and illegitimate children have received better care since the passage of this law in 1915.

Carbon Tetrachlorid and Hookworms

A critical review of the literature regarding the use of carbon tetrachloride in the treatment of hookworm disease is given by Smillie and Pessoa (*Am. J. Hyg., January, 1923, iii, 1, p. 35*) together with the result of their own investigations.

The conclusions reached are that carbon tetrachlorid, administered in 3 c.c. doses to adults, is an extremely efficient drug in the removal of *Necator americanus*. A single treatment will remove more than 95 per cent of the hookworms harbored. Doses larger than 3 c.c. are unnecessary and may be harmful, and alcoholics are especially susceptible to the toxic action of the drug. This drug has a toxic action on the host similar to that of chloroform; the symptoms being dizziness, slight nausea, headache and somnolence. These are usually transient. A later and more serious manifestation is fatty degeneration of the liver, though this rarely occurs and is seldom fatal.

Cooper and Valada (*Mil. Surgeon, Feb., 1923, lii, 2, p. 187*) report excellent success with the small number of cases they have treated and pointed out the advantages to the army surgeon in the use of carbon tetrachlorid which ordinarily does not call for hospitalization, or, if it does, for a period not exceeding forty-eight hours. For comparison with this they state that the average number of days spent in the hospital by each patient treated with chenopodium was nine; the average number of days for those treated with thymol was 12.5.

Tuberculin Tests in Cleveland Dispensary

Tuberculin testing of the clientele of the Babies Dispensary and Hospital of Cleveland, carried on by Wahl and Gerstenberger from 1907 to 1921, shows (*Arch. Pediat., March, 1923, xi, 3, p. 143*) (1) females 61 per cent positive, males 51 per cent positive; (2) infants under six months 35 per cent positive, children 36-48 months 87 per cent positive; (3) colored children gave highest percentage of positives; (4) children exposed to two or more sources of infection gave a higher percentage of positive reactions than those exposed to one source; (5) when only one source was present the mother was responsible in greatest number of cases, brother or sister next, and father the least number; (6) children giving negative history of exposure gave 15 per cent

positive reactions, those having positive contact history 44 per cent; (7) scrofula gave the highest percentage of positive reactors, then pulmonary tuberculosis, tuberculous adenitis, tuberculous osteomyelitis, tuberculous meningitis, and pulmonary miliary tuberculosis.

The writers recommend the use of a 1:1000 dilution of human old tuberculin, freshly prepared and checked on a known case of tuberculosis, and injected intracutaneously. Such a method is preferable to either the "burr" or "tattoo" methods.

World's Most Extensive Water Supply System?

The Apulian aqueduct in Southern Italy is now nearing completion after sixteen years of work. The trunk line, main, and subsidiary branches have a total length of 993 miles and supply the local distributing systems of 266 communities scattered over an area of 8,100 square miles, and having a total population of some three million people. The region served is the heel portion of the famous boot shape of the Apennine Peninsula, ancient Apulia, now divided into the provinces of Foggia, Bari, and Lecce.

This thickly populated agricultural region is fertile though arid. It contains seven towns with a population of over 50,000, the largest having 132,000 inhabitants. The Camposole Springs which serve as the source of water supply belong to a group whose combined yield is estimated at about 500 m.g.d.

An interesting account of the history of the project has been published by Gutmann descriptive of the engineering obstacles that have been overcome by tunnels, siphons, and aqueduct bridges (in the main trunk line 99 tunnels total 67 miles, 93 aqueduct bridges total 4.25 miles, and 6 siphons total 4.6 miles). (*Eng. News-Record*, March 1, 1923, 90, 9, p. 389).

Epidemiologic Survey in a Military Camp

During the August training period at the Citizens' Military Training Camp at Camp Meade, Md., in 1922, a beginning was made by P. F. McGuire and A. Parker Hitchens, Washington, D. C., (*Journal A. M. A.*, March 10, 1923), to take advantage of the unusual opportunities for epidemiologic surveys, with reference to diphtheria carriers and carriers of intestinal diseases. Cultures were made from the throats of 1,080 students, and these were studied for the pres-

ence of virulent diphtheria bacilli. In 0.83 per cent of the culture virulent diphtheria bacilli were found, indicating that nearly 1 per cent of the young men coming to the camp carried virulent diphtheria bacilli in their throats. The Schick test for susceptibility to diphtheria was made on 832 of the students, with the result that 55 per cent of them reacted positively, indicating the absence of antitoxic immunity. In spite of this high rate of susceptibility and the number of persons in close association with them carrying diphtheria bacilli in their throats, no clinical diphtheria developed during the training period. Among seven of those found to be carrying virulent diphtheria bacilli, three gave positive Schick tests; the others were immune. A study of specimens of feces from 750 of the students revealed parasites in ten, or 1.3 per cent. One of these, a young man from rural Virginia, was found to be a carrier of the hookworm. The same 750 specimens of feces were studied culturally for the presence of members of the typhoid-paratyphoid-dysentery group of bacilli, but no evidence of a carrier of a member of this group was discovered.

V. D. Clinic and Its Limitations

The venereal disease clinic, its limitations, are discussed (*Medical Officer*, Oct. 28, 1922) by Lees of Edinburgh.

Most of the clinics have been of value, but whether the cost has been commensurate with the results time can only tell. Some of the advantages have been enlightening of the public, education of the doctor, especially the medical officer of health, and have placed within reach of the general practitioners the means of early diagnosis and treatment. The physicians have also had the opportunities of perfecting themselves on all of the latest methods of diagnosis and treatment. And more, facilities have been placed in reach of every sufferer of the treatment of his disease. As a result of these activities a vast amount of knowledge has been obtained concerning the prevalence, the pathology, the cure and treatment which will prove of immense value.

Many have a fear of coming to the clinics. The importance of the initial interview is stressed. The physician in charge should see each new patient and he should endeavor to teach them the dangers of the disease by pointing out the necessity for prompt and continuous treatment, of his ability to cure them, the principles of cleanli-

ness and the advantages of a straight and sober life.

Compulsory notification of those who dismiss themselves from treatment is thought to be valuable. The difficult problem of treating seafaring men is recognized and international action is recommended. In Edinburgh the American Consul prohibits any American sailor from leaving the city if he is in an infectious stage. Difficulties are encountered in obtaining the source of infection and, when given to the medical officer, it is impossible to get the person accused to come to the clinic for examination and treatment. The author thinks the health authorities should be given the power to bring these persons in for examination and treatment. It is suggested that medical students be impressed with the importance of gonorrhea, syphilis and post graduate courses are recommended for practitioners.

Tularaemia

The Public Health Service has issued an admirable collection of reprints¹ in regard to deer-fly fever or tularaemia, the curious disease of rodents discovered by Francis two years ago.² This disease is a slow septic fever accompanied with marked prostration, lasting from three to six weeks and followed by slow convalescence with marked involvement of the lymph glands. Fatal cases occasionally occur. The disease occurs naturally in Millard County, Utah, several dozen cases a year having been reported for a number of years. It exists primarily in the jack rabbits of this region and may be transmitted from them by the biting fly *Chrysops discalis* which is probably the usual agent in transmission to man, by the bite of the rabbit louse, which presumably keeps it going among the rabbits during the winter season, by the bedbug, and by the mouse louse. The disease is also very easily contracted by market men or laboratory workers handling infected rodents.³ Of six men intimately connected with the laboratory investigations of this disease during the past two years in the laboratories of the Public Health Service every one has contracted it.

Sutler, Robert: Bacillus Tularaemia Conjunctivitis, Arch. Ophth., 44, 265, 1915. Wherry, W. B.: A New Bacterial Disease of Rodents Transmissible to Man, Pub. Health Rep., 23: 3357-3359. Lamb, Fredrick W.: Conjunctivitis Tularaemia with Report of a Case, Ophth. Rec., Vol. 26, pp. 221-226, 1917.

NEWS FROM THE FIELD

Births Gaining Over Deaths In Illinois

The Illinois death rate has been gradually decreasing since 1916, according to statistics of the state department of health. In 1916 the death rate for the state was 13.2. That year 116,536 births were recorded and 81,353 deaths. Last year the death rate was 11.3, the deaths being 75,788 and the births 133,906. The birth rate showed a corresponding increase in this period.

Births recorded in 1916 gave a rate per 1,000 of the population of 18.9, while in 1922 the rate was 20. A more thorough registration has brought the rate up, it is said.

Plan a Campaign Against Venereal Disease

As the result of an effort of the League of Red Cross Societies to establish a common plan of campaign against venereal diseases there was formed in January, 1923, between representatives of the British, Belgian, and French national societies the *Union Internationale contre le Peril Venerien*. Other associations and other countries were represented unofficially. The objectives of the *Union* will be (1) to centralize all information concerning the campaign against venereal disease, and to publish an international information bulletin; (2) to act as a link and coordinating body between various national societies combating venereal disease; (3) to facilitate the study of problems relating to the problem, to insure the general adoption of prophylactic measures, and to promote legislation; (4) to subsidize all scientific research which conform to accepted standards and to found and maintain model institutions for the study of the problem; (5) to organize congresses and conventions; and (6) to inform governments through the intermediary of national member societies of the measures calculated to promote the campaign against venereal diseases.

At Youngstown, O., the common pleas court decided recently that the city cannot exact a license fee from school cafeterias, holding that the board of education is a quasi-corporation which cannot be taxed by the municipality.

California Camp Sanitation Regulations Amended

At its regular meeting held in Sacramento, January 6, 1923, the California State Board of Health amended rules 3 and 5 of the Regulations Governing Campground Sanitation, adopted December 4, 1920, to read as follows:

Rule 3.—Fly-tight privies or water-flushed toilets shall be provided and shall be maintained in a clean and sanitary condition. Separate toilets for men and women shall be provided, one for each twenty-five men, and one for each twenty-five women, or fraction thereof, of the maximum number of persons occupying such tract at any time. No camp or picnic spot within such tract shall be at a greater distance than 400 feet from both a men's and a women's toilet. The location of all toilets shall be plainly indicated by signs.

Rule 5.—The method of final sewage or refuse disposal utilized in connection with the operation of any camp or picnic grounds shall be such as to create no nuisance. *A sufficient number of iron hoppers or basins, connected with sewerage systems or covered cesspools, to be used for the proper disposal of domestic waste waters shall be provided.*

Germany Regulates Sale of All Foodstuffs

Exerting a stringent control over the distribution of foodstuffs, the German government has put into effect a stricter regulation requiring the licensing of all those engaged in the sale of such commodities. Those licensed, according to Consul General Coffin, Berlin, must carry with them the permit, to be presented upon demand, which bears a photograph for identification purposes. Licenses are granted only when it is proved that the applicant is fully qualified as to reliability and practical knowledge to conduct a food business, and also that an economic need exists for the granting of the permit. The various State Governments have been requested to make thorough investigation into all licenses previously granted, and which are still in force.

Dr. Edward P. Hyde has resigned, effective June 30, from the directorship of research of the National Lamp Works, General Electric Company, Cleveland. Dr. Hyde will be abroad the coming year engaged on the work

of the International Commission of Illumination of which he is president.

Ground Donated for Hospital for Colored Veterans

The U. S. Veteran's Bureau Hospital for colored veterans to be opened within the next few weeks at Tuskegee, Ala., and erected on ground donated for the purpose by the Tuskegee Normal and Industrial Institute, will be manned entirely by a colored staff. The U. S. Civil Service Commission is advertising for suitable applicants for the following positions: Graduate nurses; reconstruction aides and assistants; dietitians; physicians; dentists; laboratory workers; and two pharmacists.

Enabling Blind to Become Self-Supporting

The Chicago Lighthouse for the Blind gave 43,325 hours of work to the blind in 1922. Two shops are conducted by the Chicago Lighthouse, one a weaving and the other a mechanical shop, both of which offers occupations so varied that any blind student may be employed on a graded scale. The organization is for the benefit of the permanently blind and is directed wholly toward enabling the adult blind to become self-supporting and useful citizens.

Annual Report of Public Health Association

The annual report number of the *Bulletin of the Tuberculosis and Public Health Association of Rochester and Monroe County, New York*, recounts a year of achievement which could well be emulated by other organizations of the kind. A tuberculosis case registry has been established; sanatorium occupational therapy has been promoted; open air classes have been instituted; health examinations and nutrition classes conducted; rural extension has been made of all round service and camps for children organized. Under the auspices of the Association, school nursing and medical service has become notably effectual.

A bill revising the factory law in Japan proposes to reduce the working hours for juveniles and for women; and to give them two holidays each month; to prohibit night work for juveniles; to restrict working hours for women before and after childbirth; to improve the sanitary conditions in the factories; and to give higher compensation for injuries even when the accident is due to carelessness on the part of the worker.

New Glass Withstands Great Force of Impact

A new glass is being developed for use in industrial goggles of special composition which withstands much greater impact than the ordinary laminated or hardened lenses. At present there are two types of goggle glass, the first composed of two layers of glass with an interposed film of celluloid or similar material which resists penetration if a missile breaks the glass. However, the thickness of the double lens and the color of the celluloid layer causes a reduction of light transmission that is objectionable. By a second method the glass is specially treated to increase its resistance to impact or stress.

A glass has been developed, says *Chemical and Metallurgical Engineering* which has withstood 125 or more blows on each side from a steel ball about five-eighths of an inch in diameter dropped from a height of twenty-one inches. A glass which will withstand ten blows on one side is considered satisfactory by the Bureau of Standards. In the tests reported only one lens was broken under an impact of 2.95 foot pounds which was delivered by a 1½ inch steel ball falling eight feet. This is ten times the blow the average glass will withstand.

New Schedule of Compensation for Medical Services

The Utah State Industrial Commission has issued a new schedule of medical and surgical fees permissible under Workmen's Compensation. The maximum fees as shown on the schedule may be exceeded on the discretion of the Commission, but, regardless of the maximum fees so established, the ruling of the commission will hold the physician's fee down to the prevailing charges for similar work in the community. One of the rules provide that only one-half of the scheduled fee will be allowed if the case terminates fatally within seven days of the date of operation.

Cooperative Study of Juvenile Delinquency

The reception accorded the opening of the Dallas, Tex., Child Guidance Clinic opened April 5 promises constructive results in this district from the cooperative plan for the study of juvenile delinquency under the National Committee for Mental Hygiene and the Commonwealth Fund. After an initial period of six months, the service will be continued under local direction.

Infant Mortality in Relation to Wage of Father

Such factors as economic status, conditions contingent upon housing shortage, lack of public welfare activity, and uniform influences growing out of health matters in a community where practically all are employed in a single basic industry, are well exemplified in a study just completed by the U. S. Children's Bureau of infant mortality in Gary, Ind. Additional interest is given to the study because of Gary's newness and rapid growth and the large percentage of foreign born population of diverse extraction. The infant death rate in the districts of better-housed American workmen was 90.6 per thousand births; in congested, foreign-born districts the rate was 141.2. An increase of infant mortality was noted with a fall in the earnings of the bread-winners. When the chief bread-winner's earnings amounted to \$1,850, the infant death rate was 89.4; when the earnings were between \$1,050 and \$1,850, the rate increased to 127.1; and when the earnings fell below \$1,050, the rate rose to 137.8. The heaviest toll of infant life was taken by gastric and gastro-intestinal diseases. The report concludes with the statement that much of this mortality is preventable and conditions bid fair to improve the ensuing year through measures already under way in infant welfare stations, prenatal clinics, and public health nursing.

Competitive Athletics at Studebaker Corporation

Of the value of athletics to industrial organization D. G. Baird of the Studebaker Corporation, Detroit, says in the May issue of *Industry Illustrated* states that competitive athletics may be credited with building up a morale at the Studebaker plant that is reflected in a labor turnover at the Studebaker plant of 4.2 per cent when it was 14.7 per cent in other factories through the city of Detroit in 1921, and 15.9 at Studebaker in 1922 as compared with 21.5 for the city average. Athletic work parallels in the plant the gradual transformation of apathetic, disinterested workmen into exuberance and animated interest on the part of the men. The claim is made that no other industrial organization in the country has so large a proportion of all employees participating in some form of athletic sport. The program includes athletic activities every day and evening throughout the year.

Requirements of Nutritional Specialists

A report by the Sub-Committee on Training Standards of the Advisory Committee on Foods and Nutrition of the National Child Health Council has been issued as a supplement to *Mother and Child* for May. Fundamental training in physics, chemistry, and biology is required preliminary to specialized training in nutrition, this is to be supplemented by studies in physical and chemical physiology, dietetics and household management, and practical experience in medical social work. Sociology, economics, and some bacteriology are recommended in addition to the above essentials. Clinical experience is required of nutritional specialists. The report, states the committee, is merely tentative and is to be revised as the work of providing courses in nutrition for public health workers progresses.

Few Statistics on Health Conditions of Women

There are valuable statistics on the health of men; there are comprehensive figures on the health of babies; but there are distressingly few and for the most part inadequate figures on health conditions of women. Hence the challenge of the Women's Foundation for Health to reach the goal of health examinations for one hundred women out of every hundred women in the United States. Committees on cooperation with the Foundation have been established with this objective in view with the General Federation of Women's Clubs, the Medical Women's National Association, and the Council on Public Health and Instruction of the American Medical Association. Dr. Lenna L. Meanes, director of health education of the Foundation, is chairman of each of these committees.

New Appointments in Important Fields

Dr. Willard Eugene Hotchkiss has been appointed director of the Bureau of Industrial Education of the Institute of American Meat Packers to develop a plan for the technical education of men entering the packing industry. Announcement is also made of the appointment of Dr. C. Robert Moulton, previously head of the department of agricultural chemistry in the University of Missouri, as director of its bureau of nutrition. Miss Gudrum Carlson, formerly of Teachers College assumes direction of the Bureau of Home Economics.

Great Decrease In Agricultural Population

A decrease during 1922 in the agricultural population of the United States is reported by the U. S. Department of Agriculture of approximately 460,000 persons, this estimate including not merely workers, but men, women, and children. The movement from farms to towns in 1922 was estimated at about two million persons. Births on farms were given as 925,000 and deaths as 265,000.

In the shift of agricultural population to cities and towns relatively the largest movement was in the mountain states, followed in order by New England, the Pacific, the Middle Atlantic, the East North Central and the South Atlantic States, all above the national average. Below were the West South Central, the West North Central and the East South Atlantic States.

Los Angeles Plans Third Vacation Park

Los Angeles plans to establish its third vacation field in the summer of 1923 in Sierra Park. The situation of the new playground is rugged and in certain parts the elevation is such as will require certificates of permission to take certain of the side trips that are possible. A temporary camp at Lake George is planned this year and, if this season's experience justifies the project, a permanent camp will be established later at Reds Meadows.

"Far-sighted as the playground policy of Los Angeles is, the example of practical municipal play camps has been studied and copied by other cities and by the Federal Government. Nothing has ever been done along municipal camp lines so commendable as the one planned for the Sierra National Park."

Limit Acid Pressure to Eliminate Accidents

Acid accidents must stop, says a statement in *The Chemical Age* in announcing the results of an investigation by the tank car pressure committee of the Manufacturing Chemists' Association. Tank cars carrying acids, more especially sulphuric acid, should not be subjected to a pressure of over thirty pounds per square inch but, according to the report, many cases were encountered of pressures as high as eighty pounds. Serious damage to apparatus as well as personal injury results from the prevalent neglect of heeding the thirty pounds per square inch pressure recommendation.

Suitable Places of Rest for the Tuberculous

The Tuberculosis Society of Detroit and Wayne County (Michigan) is fighting the white plague in factories chiefly through educational work with the men. The Supervisor of Industrial Health has reached 32,000 men during the noon hour in the past year and a half. The Division of Industrial Health supplements this work with research into industrial causes of tuberculosis, secures suitable places for affected men, and has classified the available places for arrested cases of tuberculosis.

Rates of Death by Accident Highest in Young

The *New England Pilot* gives the following figures from the census figures of 1915 on the deaths by accident that occur in the early years: From the age of 20 to 24, 25 per cent of all deaths are due to accident; the percentage from age 25 to 39 is 22 per cent; from 40 to 44 is 14 per cent; and from 45 to 49 is 11 per cent. Two causes operate to produce a higher ratio of accidents in the early years: Mortality from disease is then at a minimum, and accidents bear a close relation to physical activity, highest in the younger groups.

Chicago Women Physicians Organize Council

Chicago women physicians have formed an organization to be named the Chicago Council of Medical Women. Dr. Anna M. Blount was elected the first president, Dr. Lena K. Sadler, secretary, and Dr. Eliza R. Morse, treasurer. Good fellowship is a prominent objective, and the chief contribution to science will consist of the criticism and compilation of clinical experience for publication in current medical periodicals. The several specialties included in the membership of the society will thus be assured authoritative and early reports of new and interesting scientific materials.

Excess profits in the mercantile business of Benjamin Rosenthal, Chicago, will hereafter be devoted to charitable and philanthropic enterprises. The Benjamin J. Rosenthal Charities, Inc., will contribute materially to charitable enterprises now in the field, and will especially be devoted to loans in amounts up to 75 per cent of property valuations to aid wage earners in acquiring their own homes.

Atmospheric Conditions Affect Workers

The first publication of the Committee on the Atmosphere and Man, issued in November, 1922, reports progress in four lines of inquiry: Variations in influenza from city to city; mortality in New York City; factory records; and laboratory experiments.

Efforts to secure reliable records of the work achieved and the prevailing atmospheric conditions during such performance in the sixteen factories being studied have been complicated by the need to find more factories in northern climates, and to select working conditions and processes, and personnel where the factors involved will be comparable. Also, variables due to seasonal occupation need to be eliminated. While no conclusions will be drawn until data covering a period of one year have been compiled, careful studies of one kind and another have been made. It is especially noteworthy that in so many plants consistent interest in atmospheric conditions as affecting work and workers has led to the installation of instruments of accuracy and methods of observing and recording fluctuations in temperature and humidity that in themselves should be productive of very marked improvement in the hygiene of the plant.

Laboratory work has lagged for lack of men and funds, but the scheme includes cooperation between various workers in the field and a definite contribution to the study on the part of the American Society of Heating and Ventilating Engineers, the U. S. Bureau of Mines, and the United States Public Health Service.

Care Provided for Patients not Seriously Ill

A scheme for the hospital care of those not seriously ill is reported by the *Deutsche medizinische Wochenschrift* as extremely satisfactory. Sanatoriums and institutions have been converted for this use in a much simpler and less expensive manner than is required for emergent cases and the large numbers of men, women and children who are suitably cared for in such institutions are thus diverted from the greatly overcrowded hospitals in Germany. The method is especially adapted for the care of chronic affections. Economy, efficiency, and the interests of the patients are alike served by the segregation and treatment of the seriously ill apart from the chronics and the slightly indisposed or convalescents.

Injurious Substances Prohibited in Ice-Cream

A new ice cream law which became effective in Pennsylvania March 20 prohibits the use of all chemicals and doubtful substances that can prove injurious to consumers. Coconut fat and other oils are prohibited in the manufacture of ice cream, as well as the use of paraffin in chocolate coated ice cream. The use of Tragacanth gum is eliminated under the new measure, and the sale of any imitation or substitute for ice cream under a coined or trade name is forbidden.

Importance of Sanitation in Handling Pork

Conditions under which spoilage of pork hams and shoulders take place, made the object of special study by E. A. Boyer, have been reported in a recent issue of the *American Food Journal*. The organisms found were both aerobic and anaerobic in nature, and two anaerobes were found in such a large percentage, and possessed of such biochemical characteristics as to be considered largely responsible for the loss of 2,717,597 pounds of hams condemned, and \$19,597 pronounced tainted in the fiscal year preceding June 30, 1922. Bulletin No. 132 of the Department of Agriculture sets forth the importance of thorough sanitation in the handling of these products.

North Dakota Appropriations for Health

At the business meeting of the National Vocational Guidance Association, the following officers were elected for the ensuing year: Dr. Harry Kitson, president; Dorothea de Schweinitz, first vice-president; Harriet Towne, second vice-president; Professor Henry Brewer, secretary; and Arthur F. Payne, treasurer.

Three important bills have been introduced into the North Dakota Senate by the Department of Public Health. The first, known as Bill No. 54, requests legal authorization of a state department of health and a public health advisory council, calling for an appropriation of \$42,900 for a period of two years. Bill No. 55 concerns the authorization of the department of health to establish full-time cooperative county health units. The suggested appropriation is \$10,000. Bill No. 56 urges the acceptance of the provisions of the Shepard-Towner Infant and Maternal Hygiene Act; and an annual appropriation of

\$9,362.74 to meet the allotment authorized by the act.

Methods to Eliminate Diphtheria Germs from Milk

A dozen scientists from all parts of the eastern states carried out at the Borden plant at Endicott methods to eliminate permanently the danger of diphtheria infection from the milk supply of the country, says the *New York Times*.

One year ago there was a similar assemblage of scientists at the plant, who devoted their experiments to the purification of milk, with marked success, and progress has been made in the milk distributing center of the country during the past year as a result. This year particular interest centers on methods of destroying the diphtheria germ in milk. Last year's tests were on pasteurization as it relates to the extermination of tuberculosis bacilli and the typhoid germ.

Among the investigators are Dr. M. J. Roseman of Boston, Dr. McConkey of Boston, Dr. Armstrong of Washington, D. C.; Dr. D. B. White, Professor Ross, Dr. W. A. Stocking, Dr. J. W. Rice, all of Lewisburg, Pa.; Dr. North and Dr. Park of New York City, Dr. Holmquist and Dr. Miller of the State Division of Sanitation at Albany and Dr. J. P. Johnson of Homer, N. Y.

Rigid Inspection of Milk Sold in Restaurants

The Albany, N. Y., medical society has recently gone on record as wholly in favor of the model milk ordinance and solidly endorsing a campaign against "dipped" milk on the streets and in restaurants. The medical society will support thorough, rigid, and impartial inspection of farms, dairies, milk deliveries, and delivery methods as well as safe routine procedures in the pasteurization of milk as required by the model law.

Accurate Tables for Refrigeration Processes

An investigation by the U. S. Bureau of Standards of the properties of anhydrous ammonia in the interest of refrigerating industries has so far progressed that it is now possible for the department to compile a set of accurate tables for engineers' use in designing and studying the operation of refrigerating machines. All of the properties necessary for such compilation have now been determined within the range of pressures and temperatures ordinarily encountered

in practice. Tests conducted during the investigation showed that most commercial ammonias contain less than 0.1 per cent of impurities.

American Dietetics to Meet at Indianapolis

The American Dietetic Association announces the date of its annual meeting to be October 15 to 17, at Hotel Claypool, Indianapolis, Ind. The officers of this organization are: Mrs. Octavia Hall, Andalusia, Ala., president; Mrs. Hallie B. Sorsette, public health dietitian service, Washington, D. C., first vice-president; Miss Breta Luther, secretary; and Miss Anna Bolter, 824 E. Forty-seventh Place, Chicago, treasurer.

Red Cross Changes Names of Sanitary Stations

In the interest of precisely descriptive terms for the use of Red Cross workers helping to fight epidemics The *World's Health* proposes to substitute "sanitary zone" for the expression "sanitary barrier" now in use, and "exchange and observation station" for "quarantine station." The changes in terms would imply a much more flexible system of sanitary supervision of frontiers. Efforts would be limited to establishing a zone where the severity of medical inspection can be redoubled and where the slightest suspected case of disease can be placed under observation. At the exchange and observation stations trained epidemiologists will follow up all suspected cases and trace all lines of communication. The new plan was the outcome of a study of the subject made at the Eastern European Health Conference held at Warsaw in 1922.

Funds for Henry Phipps Psychiatric Clinic

Sufficient funds to place the Henry Phipps Psychiatric Clinic on a full-time basis are practically in hand, as all but \$35,000 of a fund of \$2,000,000 has been raised. This, it is confidently expected, will be easily raised before the time limit set by the anonymous donor. In addition to the initial gift of \$1,000,000, the Rockefeller General Educational Board has contributed \$750,000 and Mr. E. W. Harkness of the Standard Oil Company, \$125,000. Other contributions have amounted to \$90,000. With the exception of the psychiatric department in the University of Iowa, this will be the only department of psychiatry in a medical school on a full-time basis.

HEALTH PUBLICATIONS REVIEWED

The Public Health Service, Its History and Organization

This volume by L. F. Schmeckebier, belongs to a series of monographs prepared on a uniform plan giving a detailed discussion of each of fifty or more services of the United States Government, issued under the auspices of the Institute for Government Research. (Service Monographs of the U. S. Government, No. 10.) It reviews in complete and exhaustive fashion the history, activities, organization and personnel of the United States Public Health Service, with full citations of the text of the various laws which have been passed in regard to this service since its establishment as an unorganized marine hospital service in 1798.

The story of the development of the Public Health Service is a fascinating chapter in the history of governmental function and it is of particular interest to see how the usual tendency to incorporate the care of the individual in a plan of public health protection is here reversed, the hospital function having come first and being expanded into a comprehensive program of sanitation. The account of the activities and organization of the Public Health Service is clearly and effectively presented, and the volume will form an invaluable addition to the library of every student of public health.

The Johns Hopkins Press, Baltimore.

Health Building and Life Extension

This book, by Eugene Lyman Fisk, is the outcome of a survey of health conditions in industry undertaken by the Life Extension Institute for the Committee on the Elimination of Waste in Industry of the Federated American Engineering Societies. It deals with the importance of physical disability and the causes of such disability and the preventive, remedial and constructive measures which may be used for its control. The book contains a large amount of statistical material but this material is not very critically selected and is presented in a rather uninteresting fashion.

Macmillan, New York, 1923.

Tobacco and Mental Efficiency

Professor M. V. O'Shea's book represents the first formal publication issued in the name of the Committee to study the Tobacco Problem, organized in 1918 with Dr. Alexander Lambert as president, and will be read with keen interest by those who have been interested in this question, either for or against the fragrant weed. The first half of the book is made up of more or less desultory opinion from a group of 156 prominent persons in regard to their use of alcohol and their opinions as to its effects on themselves and others, an accumulation of amusing but quite unimportant gossip. The second part includes a statistical study of the relation between the school and college records of smokers and non-smokers and is of real interest. An analysis of a group of two thousand pupils indicates a correlation between smoking and scholarship of .51, which is apparently significant of a real relationship, although detailed figures are not given in the present volume. The question of course still remains open whether the habit of smoking was a real cause of interference with scholastic record or whether as seems rather equally likely the smoking was a symptom of a general tendency toward non-scholastic interests.

The third part of the book is based on some exceedingly interesting studies in the psychological laboratory in which eighteen subjects were required for repeated experimental periods to smoke a pipe which was either filled with tobacco in the usual way or warmed by an ingenious electrical arrangement so that the air drawn into the mouth was about the same temperature as that of ordinary smoke. The subjects were blindfolded and were apparently quite unable to tell whether they were smoking tobacco or not. An analysis of the physical condition of the subjects on the smoking and non-smoking days indicated that the smoking had a very definite effect on the heart rate, the pulse rising on the average six beats on the smoking days. There is also reasonably clear evidence that the steadiness of motor control as evidenced by the ability of the subject to hold a stylus was unfavorably affected by tobacco. The great bulk of Pro-

fessor O'Shea's tests dealt with various mental functions and these he thinks indicate that "taking a large number of individuals tobacco will slow down and disturb the intellectual processes of the majority."

The reviewer is not inclined to think that the figures bear this interpretation on account of the enormous variation in individual readings. Unfortunately, no calculations of probable errors are given. There were nine purely mental tests however and altogether 122 individual results reported for these nine tests (some of the eighteen men failed to take certain tests which accounts for there not being 162 such records.) Of these 122 tests results, each reported for a single man, sixty-two showed an unfavorable effect of tobacco and sixty a favorable effect. It would be safe to predict under these circumstances that computations of probable error would wipe out most of the differences observed. Nevertheless Professor O'Shea and the committee with which he is cooperating deserve the highest credit for making a beginning at the scientific study of this important problem and should be warmly complimented on the fair and impartial attitude which has been preserved throughout the work.

Macmillan Company, New York, 1923.

Stammering, Cleft Palate Speech, Liping

This little book of 101 small pages, with wide margins, by Kate Emil Behnke, is the product of three successive authors, each author improving and enlarging upon his predecessor's work; in fact, the book represents the work of three generations in the same family.

The first part has been written by Emil Behnke, the head of the family; the second part was written after the author's death by Mrs. Behnke, the wife of the author, and the third part by Kate Emil-Behnke, the daughter.

The book does not contain any revolutionary research on stammering, nor does it offer any new ideas in the treatment of stammering. On the whole, however, it makes interesting reading to people who are concerned about this malady which affects a goodly portion of our population.

Chicago Medical Book Co., 1922.

Rules of Recovery from Tuberculosis

This little hand book by Lawraon Brown, on "Rules of Recovery from Tuberculosis," may profitably be read both by patients who are afflicted with tuberculosis and by people who do not suffer from the disease for it is a treatise on regular habits and healthy living.

The author does not attempt to prescribe for the patient, but throughout the book offers sound advice that is as useful to the patient as drugs. There is good reason for the book having gone through four editions in the short space of time.

Lea & Febiger, New York, 1922.

Feeding, Diet and the General Care of Children

The book by Albert J. Bell, M.D., on "Feeding, Diet and the General Care of Children," was evidently written during the present epidemic of health publication. It is not particularly interesting or valuable.

F. A. Davis Company, Philadelphia, 1923.

Louis Fisher on The Health Care of the Baby

In the reviewer's opinion this is a poor book although it has gone through thirteen editions. Many methods described therein will be challenged by other pediatricians.

Funk & Wagnalls, New York, 1922.

The Problem of Population

This book by Harold Cox is a clear and convincing, if not particularly original presentation of the case for Neo-Malthusianism, emphasizing the importance of controlling the growth of population as a preventive of war, social distress and racial degeneration.

G. P. Putnam's Sons, New York, 1923.

Athletes Find Use for New Jersey Armories

A plan outlined in the current issue of the United States *Army Recruiting News* contemplates extensive use of armories in the state of New Jersey by various organizations, such as the American Legion, grammar and parochial schools, preparatory and high schools, and industrial leagues for athletic activities that constitute one of the widest movements yet undertaken in the interest of recreation.

There will be sectional championship meets held in the track and field events, and after South Jersey has decided its winners they are to be sent against North Jersey to decide who will represent the State. This plan will be followed not only for the National Guard but for the American Legion and all schools and organizations participating. In this way all will be given a chance to compete for the State championships, which should develop some excellent athletes, it is believed.

Boxing will hold a conspicuous place in this program, and each organization will hold a series of elimination bouts to decide who will represent it in the tournament for the state championship. All classes of boxers will be entered from flyweight to heavyweight. The armories all over the state will be thrown open to those properly enrolled to use them for training purposes during the afternoons and on evenings when such occupancy will not conflict with drills of the National Guard. Regular army officers on duty as instructors with the Guard will be present to lend their assistance to those in training and to see that they get properly started in their athletic endeavors.

In this connection it is hoped that in the near future, says Frank A. Wandle, supervisor of recreation, Sec-

ond Corps Area, all the athletic training teachers in this work will be called together for a month's study and training under Lieut. Col. H. Koehler of the United States Military Academy. The idea behind this is that the physical training of New Jersey's young Americans would thus be coordinated and systematized throughout the State. Colonel Koehler's system, which has been so successful at West Point, is considered the best extant and is being used in many places throughout the country. The benefits from the adoption of a uniform plan of physical training must be obvious to all, as the young ones could then receive their recruit instruction and go from class to class through school and advance step by step in their physical training at the same time.

With the announcement of this new plan for the use of the State armories, it was made clear that they are not going to be thrown open to every one without regard to discipline. The soldiers will naturally have preference, and on drill nights will probably have programs of their own. Other nights will be set aside for general participation by residents, and the whole program will be supervised by General Gilkyson. The decision to open the armories especially for the use of the young man has awakened a great deal of interest in the National Guard.

Respiratory Protection in Street Manholes

Workers in street manholes for telephone and electric power conduits, sewers, gas and water mains, often encounter irrespirable atmospheres due to leakage of artificial or natural gas, sewer gas or gases caused by electrolysis. Inquiries received by the Bureau of Mines and conferences between engineers who have to deal with manholes and members of the Bureau have disclosed the need at times of respiratory protection for workers in manholes. It is planned to secure samples of contaminated air from manholes and to test hose masks in them. Recommendations for protection of workers in manholes will be published. This experimental work is being conducted at the Pittsburgh, Pa., experiment station of the bureau.

Illinois Institute for Nurses

Announcement is made of an institute for nurses to be held in Chicago, September 3 to 14, inclusive, under the auspices of the Illinois League for nursing education.

Significance of *B. Coli* in Water

(Continued from Page 527)

In 1913 and 1914 Rogers and Clark, of the United States Department of Agriculture, began what proved to be a fundamental piece of research. Using highly refined bacteriological and chemical methods, they demonstrated conclusively that the so-called *B. coli* group, which had previously been considered one group of bacteria, really comprised two separate and distinct groups, one representing "true *B. coli*" and the other a similar but distinct "aërogenes group." These two groups, which gave more or less identical reactions by tests previously applied, were distinctly differentiated by different ratios of hydrogen to carbon dioxide in the gas formed and by different hydrogen ion concentrations established in special media under standardized conditions. The differentiation as first made by Rogers and Clark required rather elaborate apparatus and technic, beyond the reach of most water bacteriologists; but subsequently, as a result of work by Dr. Clark and others, the technic was greatly simplified, so that the differentiation can now be made by very simple tests, requiring no special apparatus.

Applying these tests to large numbers of cultures derived from different sources, Rogers and Clark found that the colon bacilli found in feces, whether human or animal, belonged almost exclusively to one group, which they called the "fecal group," while the colon-like organisms found on grain belonged usually to another group, which they called the "non-fecal" or "grain" type. Their work is still relatively new, but already it has been confirmed by quite a number of independent observers, and, so far as I am aware, all subsequent work tends to establish the original conclusions arrived at by Rogers and Clark: that the "fecal type," or true *B. coli*, is predominant in fresh feces and in material exposed to fecal contamination, while the colon-like organisms found on grains and in unpolluted soil almost invariably prove to belong to the "aërogenes group."

Determine the Type

As to the significance of this, a good many sanitarians appear to have the impression that it renders the ordinary test for *B. coli* less significant than previously. While this may be a natural viewpoint, it is not justified.

It is true that a positive test for *B. coli*, made according to present standard methods, may indicate the presence not of true *B. coli* but of the nonfecal aërogenes type. But this has always been true, though not previously recognized; and the probability that a positive standard *B. coli* test in water means fecal contamination is just the same now as it was ten years ago. Moreover, in cases of doubt or special importance it is now possible to carry the test further and determine whether the organism is true *B. coli* or aërogenes. Also, this recent work appears to offer a satisfactory explanation of the finding of so-called *B. coli* in the past in situations where their presence could not be satisfactorily accounted for as due to fecal contamination. Presumably these organisms were of the aërogenes type, not true *B. coli*.

The American Public Health Association has not yet made it obligatory in their standard methods to differentiate *B. coli* from aërogenes, but they describe the technic, so that any reasonably well trained bacteriologist can make the differentiation. In the absence of such differentiation a positive test should be interpreted as heretofore; that is, as constituting strong presumptive evidence of fecal contamination. Admitting that this is not positive proof, the benefit of the doubt should be given to the public and the contamination should be considered as of fecal origin unless evidence is brought forward to the contrary.

So far the discussion has referred only to demonstrating the presence of contamination with excreta; but even granting that the presence of excreta is demonstrated and the extent of the contamination measured, this still is not equivalent to measuring the danger of the water in terms of the probability that it will cause infection. For this several further steps are necessary.

First, it is necessary to differentiate between excreta from lower animals and that from human beings. As this can not be done by means of chemical or bacteriological tests, it requires a survey of the sources of contamination to which the water is exposed. This may afford more or less definite information. For example, *B. coli* is of much more dangerous significance in a well obviously contaminated from nearby privies than one

not subjected to contamination from privies but located near a heap of stable manure.

However, even the demonstration that water is contaminated with human excreta does not necessarily indicate that it is immediately dangerous and falls far short of measuring its danger. A well or spring grossly contaminated from a privy and used by a small number of people may not be actually dangerous merely because none of the people contributing to its contamination is infected with any pathogenic organisms. Such a well, though very offensively polluted, may not cause any infection within a generation. On the other hand, it is quite certain that a river such as the Ohio, which constantly receives sewage from several millions of people, always contains typhoid bacilli and other pathogenic intestinal bacteria. This is necessarily so because among the millions of people whose excreta reach the stream there are always a very considerable number harboring pathogenic bacteria, either as active cases or as carriers. The only question as to such water is not whether or not it is contaminated but to what extent.

Sources of Pollution

But even when it is known that a water contains typhoid bacilli or other pathogenic bacteria, this still does not constitute an active measure of its danger. Even if we knew the exact number of typhoid bacilli per thousand liters of water, we still would not know what proportion of the people drinking this water would become infected, because we know practically nothing as yet regarding the dosage necessary to cause natural infection. Nor have we more than the vaguest ideas as to the relative danger of waters containing different numbers of pathogenic bacteria. For example, if a water containing ten typhoid bacilli in a certain volume will cause infection in 10 per cent of the people who drink it, it by no means follows that a water containing one typhoid bacillus in the same volume of water will cause 1 per cent of infections. Conceivably it might still cause the same proportion of infections as the more highly contaminated water, or it might cause none. We simply do not know the effect of varying dosage of infective organisms.

The nearest approach that has been

made to the exact knowledge of the danger of water supplies, in terms of the number of cases of infectious disease which they will cause, has been made not by bacteriological studies but by epidemiological observations. For instance, our estimate of the danger of raw water from the Ohio River is based not on its bacteriological examination but on past experience in cities where this water has been used; an experience which has shown that one per cent or more of the consumers develop typhoid fever each year, whereas the same cities when using more or less adequately purified water supplies have not suffered much more than one-tenth such a typhoid incidence rate.

I have dwelt upon the difficulties and indirection of estimating the danger of water supplies, not with a view to casting doubt upon the value of bacteriological examination but merely to emphasize the point that the sanitarian who attempts to estimate the quality of a water supply must take into consideration not only the bacteriological evidence of pollution but also the character of the sources from which the pollution presumably comes.

In extreme cases an interpretation

may be very simple. For instance, a water which consistently gives negative *B. coli* tests and very low bacterial counts may be pronounced safe so far as infection is concerned without knowing anything more about its origin. Equally, the water from a stream known to receive the sewage of a city a short distance upstream may be condemned as unsafe without the formality of a bacteriological examination. It is the intermediate cases which are difficult; those in which bacteriological examination shows moderate contamination and a sanitary survey reveals exposure to possibly though not certainly dangerous contamination. As to such cases there is always room for perfectly legitimate differences of opinion, which can be proven only when epidemiological evidence shows that the water is responsible for infection or that it is causing none. It was circumstantial epidemiological evidence which first proved the agency of water supplies in spreading infection, and it is evidence of the same kind, rather than direct bacteriological evidence, which best serves today to establish and measure the danger of a water supply.

Food Fads and Health

A FEW "swallows do not make a summer"; neither do a few swallows make a balanced meal and it is for this reason that people who need to know the true values of the foods they are eating should look to the scientists for the information rather than be misled to believe that a certain food practice has a mysterious or unusual importance. Fasting has its merits in individually selected cases, but the voluntary elimination of this factor or that in the daily diet may have cumulative effects undreamed of by the uninitiated. A broadcast recently sent out by the New York State Department of Health illuminates the subject of the ubiquitous food fad and its possible effects.

The fact is that most fads represent partial or half truths—and he is wisest who relies not alone upon his own beliefs and preferences as to the real value of any single practice, but who is alert to find out the estimation or value placed on it by true scientists who have no other motive than to search for truth and the improvement of human kind.

One of the most common practices is the "going-without-breakfast" fad, which has been especially developed among young people, notably girls.

The normal person needs a nourishing breakfast to draw on for energy used in the day's activities and it is very doubtful if an individual can or does get ample nourishment from two meals a day.

The aversion which some people show to milk and eggs, as such, may be counteracted by always serving these foods in combined or cooked form. Milk will serve the needs of the body as well in cocoa, soup, custard, or sauce as if it is served plain from a glass. The necessary thing is to get at least a pint of it into the daily food intake. An egg is an egg whether it is in a custard, or is eaten boiled, noached, or scrambled. It is worth knowing that the yolk of the egg will furnish one-tenth of a day's requirement of iron and that it would take one potato or two tablespoonfuls of dried beans or one-third cup of baked beans or one-half cup of oatmeal or three figs or six prunes and eight dates or one tablespoonful molasses, or five young carrots, or about one tablespoonful of spinach to supply the body with as much or more iron. Egg yolk also is a good source of the vitamins A and B, now known to be essential to growth and normal development.

After one has jogged on toward the age of thirty-five or forty and finds himself possessed of more girth than can be viewed with pride, all sorts of reducing fads are often resorted to—such as "counting calories," the "hot

water taking" fad—the "raw food" fad and numerous others.

Each of these fads probably contains an element of truth which can readily be pointed out. A calculation of the number of calories or heat units consumed in one's daily energy expenditure is valuable and illuminating in indicating whether one's intake and outgo balance—but it is of equal importance to know if one's calories come from the right source and in the right proportion. Such calculations are too involved for the untrained person to be interested in, as a rule. Calory calculation is a starting point, but an indiscriminate choice of foods on the basis of calories alone is dangerous and may be harmful.

Equally dangerous is the hot water taking fad. "Water internally, externally, and eternally" is a catch phrase which has captured the imagination of many. Hydrotherapy, is recognized by physicians as of especial value in some cases—but the judgment about when to use it and how much to use should be left to the decision of a physician.

The raw food fad apparently has some justification insofar as it represents a reaction against bad cooking. Poorly cooked vegetables are more difficult to digest than properly cooked ones—but the stomach does attempt to digest them; while insofar as we know uncooked root vegetables are in general "ignored and passed on" by the stomach. The least we can say about the raw food fad is that it is without scientific basis. And there is always the very real danger of typhoid fever from foods that have been grown in soil contaminable with sewage. For this reason all uncooked vegetables such as lettuce, celery and water cress should be carefully washed.

The sour milk fad had its vogue a few years ago due to the value assigned to it by the French scientist, Metchnikoff, as a means of getting rid of the germs causing intestinal putrefaction. It has proved of value in the treatment of certain cases of intestinal trouble, but for the normal person sour milk is useful only because it has the same constituents as sweet milk.

Strict vegetarianism is probably not practised by very many people, although the philosophy is held by some that we should not sacrifice animal life for food. These same persons wear shoes made from animal hides and silk from the silk worm, however, and most of them use eggs, milk, and cheese; and the nuts, cereals, and vegetables of which their diet mainly consists have certainly had life and would have life if they had not been used as food.

The truth of the matter is that many persons eat more meat than should be eaten. "Meat once a day" is a limit which can be safely adhered to. But laboratory study has shown that the proteins or the body building constituents or content of foods, from animal sources, have certain higher value than do those from vegetable sources and the superior palatability of meat is generally recognized.

The true test of the value of any food lies in what it can contribute

to the sum total of man's well being. Exact science has now replaced the fanciful ideas that carrots will make one beautiful—that crusts will make the hair curl, and that fish is brain food.

It is said that a certain number of people still believe that rheumatism may be avoided by carrying a red kidney bean or a horse chestnut in the pocket, and that others carry an onion in the hair for the relief of headache. Such practices are often founded on hearsay or adopted because of a single instance of a person who is believed to have had success with it.

It behooves us to avoid what can not be confirmed or tested by scientific proof, recognizing that health is largely a matter of judicious combination of fresh air, work or exercise, recreation, rest and food of suitable kinds and in sufficient amounts.

Widespread Malnutrition Reported by Health Council

At least 20 per cent and, according to some estimates 33 per cent, of the school children of the country are suffering from malnutrition, as general physical under-development is commonly designated, says the Advisory Committee on Foods and Nutrition of the National Child Health Council in a report published by the United States Public Health Service, which co-operated in its preparation.

Malnutrition, continues the report, is not confined to any one class or race; in some cities it is apparently as prevalent in the homes of the well-to-do as in those of persons of more limited means. The condition is evidenced not only by weight and growth records but also by listlessness, lack of color, dullness, and sometimes by restlessness and irritability.

Environmental conditions which interfere with sufficient sleep, lack of fresh air, and even constant nagging may cause under-development, and their correction may result in remarkable gains, says the Health Service in discussing malnutrition.

Cases of malnutrition that do not yield to simple corrective measures may require long medical supervision, and in any event, preventive measures are much better than curative ones, continues the Service. Health education in the schools will go a long way toward preventing malnutrition, not only in the pupils themselves, but will also, if the results are brought energetically to the attention of parents, usually react to the benefit of younger children of pre-school age. And the younger the child, the more easily are proper health habits learned and the more valuable they are.

Health education may also be

spread by well qualified speakers, by magazine articles, moving pictures, health plays, and exhibits that vividly bring home the results of malnutrition and the often amazing improvement derived from corrective measures.

In this connection may be instanced the news just received by the United States Public Health Service of the very marked success of a nutrition exhibit sent by it to Brazil as a part of the international centennial exposition recently held at Rio de Janeiro. This exhibit consists of two tables, at each of which two large dolls, supposed to be 10 years of age, sit at dinner. The meals spread for them look equally appetizing. One of them, however, includes no milk, no green vegetables, and no fresh fruit. The dolls at this table are a little better dressed than those at the other table; but their faces, though they still show evidences of former beauty, are colorless and their eyes are dull and are underlined heavily with dark half-moons. The dolls at the other table, on the other hand are rosy cheeked, bright and laughing.

The effect both on parents and children was very striking. Day after day the space before the exhibit was crowded by mothers or teachers, pointing to wide-eyed children the difference in the appearance of the children, who drank milk and ate proper food and those who did not. And a very large proportion of the adult visitors came back again and again, bringing other children with them.

Hospital Bed Capacity of New York City

Dr. C. E. Banker has presented in the January issue of the monthly *Bulletin* of the New York City Department of Health an article on the hospital bed capacity of the city. Study of the files of the Division of Institutional Inspection show that there are 216 hospitals in greater New York with a bed capacity of 44,793. Twenty-five of the hospitals are public, 121 semi-private, and seventy private. The public hospitals have 24,288; the semi-private 18,767; and the private 1,738 beds. Manhattan has more hospital beds than Brooklyn, Bronx, Queens, and Richmond combined.

Attention is called to the bureau maintained in the office of the Commissioner of Health during the 1918 influenza epidemic which obtained, daily, from the hospitals of the city information regarding the number of vacancies which they had, and in turn

informed both lay and professional inquirers where beds might be found for those in need of hospital treatment. If some such system were in operation at present, handling information regarding the number of beds available for various types of cases at the hospitals, it would do much to correct the present situation in which some hospitals are often overfilled and obliged to resort to makeshift accommodations while others have too many of their beds vacant.

A classification of the number of beds available for special diseases follows:

For—	Bed Capacity
Women and children (including maternity hospitals).....	3,680
Mental and nervous diseases (including mental defectives).....	10,523
Cancer and allied diseases.....	201
Contagious diseases.....	2,317
Incurable and chronic cases (exclusive of tuberculosis).....	1,613
Tuberculosis.....	2,495
Diseases of eye, ear, nose, and throat.....	639
Orthopedic defects.....	435
Public health service and care of soldiers, sailors and marines.....	3,093
Convalescents and those on special diet.....	88
Diseases of the digestive system.....	51
Special study of selected diseases.....	60
	25,180

The difference between the total bed capacity of the city (44,793) and those found in the special hospitals (25,180) should represent the "general" bed capacity of the city. It must be remembered, however, that any such classification is very difficult to make and that many of the small private so-called "general" hospitals would have to close if it were not for the disproportionately large number of maternity cases that they handle.

Scholarships for Nurses

The American Child Health Association has offered a series of scholarships for nurses for the school year of 1923-24 and for the summer schools of 1924. The scholarships are designed for nurses with experience who are especially interested in furthering the cause of child health through nursing.

Study may be carried on in colleges, normal schools and university departments of nursing, in post-graduate courses in obstetrics, pediatrics and orthopedics in schools of nursing, in practical experience in prenatal, obstetrical, infant the subjects and standardization of method having to do with both pre-school and school work.

Awards for the fall courses are to be made this month. Information can be obtained from the Association by a request sent to 370 Seventh Avenue, New York City.

Organizing to Salvage the Mental and Nervous Derelict

(Continued from Page 526)

requires the closest kind of observation and study as to the causes of epilepsy, the possibility of controlling it by medication or other means, but a mental condition as well, for which the environment is mainly responsible. It may positively be asserted that removal to an appropriate institution with proper medical care would solve the nervous manifestations, since the conduct disorder is a superimposed phenomenon and not inherent in the epileptic disorder itself. Unfortunately, existing public institutions are overcrowded, and the father has not the means to send the boy to a private institution.

Case 4.—S. A., a young girl, age twenty, born in Syria, had a public school education and is employed as a milliner. About a month ago she was reproved by her forelady for spoiling a piece of work. She became hysterical and cried. Although it was later proved that a mistake had been made and that another girl was to blame, her attitude did not change. She continued to be nervous, cried and shivered. On occasions she felt her fingers were stiff and she could not move them. She rested at home for two weeks but at the end of this time could not resume work. She was annoyed by noises on the street, lost her appetite, felt nauseated and vomited frequently. She worried about her mother who is in poor health. An offer was made to send her to the country but she refused to go because the food there is not "Kosher." A situation like this is one toward which the physician is bound to feel great sympathy. A young girl of pleasant personality and intelligent, is face to face with a serious problem in her life. It will be easily understood that such a trifling occurrence in the shop could not produce such marked nervous phenomena and that the real cause lies deeper. In other words, speaking psychoanalytically, there has occurred a shifting of the center of gravity from unconscious motivation to conscious thinking and that prolonged psychological labor will be required to unearth the hidden forces which brought about this nervous condition. The existing clinics are totally inadequate to meet such wants since for the treatment of such conditions a staff of highly trained psychotherapists would have to be employed. Yet it is clear that it is the duty of the community to take care of nervous patients as well as of mental cases.

A problem arising in connection with mental cases among Jews as well as others concern those immigrants who shortly after arrival in this country become insane; if committed to a state hospital, they are liable to deportation, a procedure which brings immense grief and misery to the family of the afflicted. This applies particularly to those patients who are almost sure to recover within a few weeks or months.

One of the most serious difficulties about which help is often sought relates to the problem of the abnormal child. Too often the crux of the situation is the lack of an intelligent and sympathetic attitude towards the child's shortcomings, a failure to appreciate the needs in the individual case, and the lack of an earnest desire and effort to co-operate in the correction of the existing bad habits. This is particularly true of immigrant parents of native-born children.

Advice is frequently sought at mental hygiene clinics in reference to domestic difficulties of various kinds. These require painstaking care in studying the multitudinous problems presented. It is evident that only a thorough-going analysis of all the factors in given cases can afford a sure basis for useful advice and service. There are numerous borderline cases, mild temporary mental disturbances, cases of psychoneuroses whose lives are rendered miserable unless proper and timely treatment can be given.

Only a small number of the insane actually require removal from their homes and confinement in an institution. The screaming, violent maniac, the paranoiac who is homicidal, and the melancholic who would take his life, stand in need of commitment. The majority of cases of the dementia praecox group, nearly all mildly depressed cases and the large group of borderline cases, the conduct disorder group, etc., can best be treated at home with the aid of such means which a mental hygiene center should supply. Indeed, in a number of cases of dementia praecox, for instance, it can be shown definitely that removal to a hospital or sanatorium is distinctly disadvantageous. These patients are commonly introspective and shy, lose contact with the world, and retreat within themselves where they live in a world of fantasy far removed from the realities of life. If to this psychic anomaly is added the strangeness of an external situation, there is produced an intensification of the "unreality complex" from which they suffer. There are mildly depressed patients, who when transferred to a detention hospital or state institution, suddenly become mute and pass into a state of stupor lasting for months. This results from the severity of the shock of the changed external situation. In a case of a recurrent benign stupor the discussion

in the patient's hearing of his commitment resulted in a practical recovery within a few days; the fear of commitment was strong enough to overcome the apathy of the stuporous state.

It is essential to separate the symptoms inherent in a disease from those accidental and concomitant, brought on by the stupidity and ignorance of those in charge of the patient. To rush a patient to an institution on the advice of an irresponsible medical attendant is a serious blunder. Instances could be cited in which the outraged finer sensibilities of a patient have never been recovered from and that for years a stubborn hatred toward the family was practically the only outstanding mental abnormality remaining. Happily, modern psychiatry has profited by the lessons of experience and today we find a progressively larger number of mental cases taken care of in out-patient clinics than ever before. The state hospitals have been paroling an increasing number of patients each year, fully realizing that if the patient is to "recover" he must do so within his original environment, and in the milieu which gave origin to his symptoms.

It may be asked, of what use is a hospital after so much has been said in disparagement of hospitalization of patients? The answer is that in psychiatric practice there frequently arise situations in which temporary detention becomes imperative. Often a case can best be studied only when under continued observation in a hospital over a period of days or weeks.

Five elements are necessary for the proper organization of mental hygiene service to a community. These are: (a) an all-year educational campaign, (b) adequately manned clinics, (c) a convalescent home for mental and nervous patients, (d) a workshop equipped for occupational therapy, and (e) a psychiatric or mental hygiene institute functioning in conjunction with the other items and serving as the mental hygiene center of the community. Some of these items have already been established in various communities. However, until a complete program is initiated, whether through the efforts of public authorities or private citizens, or through a combination of both, the attempt to serve mental and nervous cases will continue to be seriously hampered.

Vitamin B as a Factor in Nutrition

(Continued from Page 510)

the best way to explain the relationship is by way of illustration. A dog is fed a purely artificial mixture of food-stuffs, this mixture containing everything that the animal requires for proper nutrition *except* vitamin B. The amount of food thus offered is carefully weighed each day in order to determine the exact amount that is eaten. For several days the dog eats immediately all of this food mixture when offered. After a period of from five to fifteen or twenty days, depending probably upon the amount of vitamin B stored in the tissues of the animal, a lack of interest in the food is displayed; it may be left in the cage for three or four hours, but the animal either will eat only a part of it or will refuse it absolutely. If, at any time after the loss of appetite has revealed itself, the dog be given a sufficient amount of some source of the substance which the food mixture lacks, namely vitamin B, the appetite is completely restored, and the animal eats ravenously the same food that had previously been refused. This result cannot be due to an altered taste of the food offered, for the vitamin may be placed in the stomach by means of a stomach tube and the same result obtained. Furthermore, the taste of the food may be altered by mixing with it a small amount of meat extract which does not contain vitamin B: when this is done the animal may eat the changed food mixture one day but refuse it thereafter. Only the administration of a sufficient amount of some source of vitamin B to such an animal can bring back the desire to partake of food. As if this were not sufficiently striking, it has been learned further, that the amount of vitamin B required to restore the appetite to such an animal and the amount which must be eaten daily to maintain the appetite without failure, bear a very definite relationship to the size of the animal, if the size be estimated in terms of the body-weight: in other words, the quantity of vitamin B given is important. When the dog is offered this vitamin B-free food mixture and daily given apart from it a sufficient amount of the vitamin, the desire to eat may be maintained without failure for many

months; animals have been fed successfully in this fashion for over six months. These experiments, quite apart from the data they furnish regarding the relationship between vitamin B and the appetite, constitute a complete demonstration of the vitamin hypothesis.

The problem of combating anorexia, i. e., loss of appetite, is one that confronts the physician, and nurse, as well as the dietitian who has the feeding of an institution or a family of active children as her responsibility. Now it would involve taking an unwarranted step in reasoning to conclude from the demonstrated relationship between loss of appetite and vitamin B, that a lack of this vitamin is always the cause of the loss of appetite. There are doubtless many causes of anorexia other than vitamin B deficiency. Nevertheless the rôle, which this vitamin plays in maintaining the desire to eat, has some very definite applications.

Many marasmic infants, undernourished, apparently unable to thrive on the food offered, have shown remarkable improvement in their general condition and a resumption of growth as a result of the addition to their foods of liberal amounts of materials rich in vitamin B.⁶ While it is difficult in such cases to conclude absolutely that the appetite has been affected, the behavior of the child after receiving the vitamin, particularly the new interest it displays in the bottle and in feeding, suggests that the therapeutic agent, namely vitamin B, has acted to restore the desire to eat.

It is quite likely that the administration of vitamin B to convalescents who have lost the desire for food would prove beneficial to such individuals. When it is realized that most of the common foods which are included in the bill of fare followed in feeding sick individuals and convalescents, are poor in their content of vitamin B, and that the absence of this dietary essential from the food over any extended period affects the appetite, greater care will be taken by physicians and dietitians to include liberal quantities of good sources of this vitamin in the menus that are prepared for the sick and the near-sick.

Just how the continued absence of vitamin B from the dietary brings about a loss of appetite is not easily explained. It has been suggested that the vitamin functions to stimulate the various digestive glands to activity, but careful experiments to determine whether such is the case have given negative results.⁹ Another possibility is that the so-called hunger contractions, which the normal empty stomach exhibits at intervals, disappear or are markedly influenced when vitamin B is absent from the food for any protracted period. Experimental investigation of this possibility is as yet unfinished,¹⁰ but the observations already made suggest that while the normal motility of the stomach is affected after a time by vitamin B deficiency, this relationship is not intimate enough to warrant the conclusion that disappearance of hunger contractions is the immediate cause of appetite failure, the lack of vitamin B serving as the remote cause.

The field of research into the physiology of vitamin B is new and should therefore hold some promise of interesting discoveries for the future. "The greatest good for the greatest number," which has been said to be one of the ideals of a democracy, will result from such discoveries, however, only when a cooperation of physiologist, physician, nurse, dietitian, public health worker, and all who serve in related fields to promote the physical well being of the nation's citizens, is realized.

Chemists Suggest Safe Name for Wood Alcohol

The attempt to establish the name methanol in place of wood alcohol, for the better protection of those not educated along chemical lines, has received impetus by a recent action of National Wood Chemical Association. The Board of Governors has adopted a resolution recommending the use of the former term.

Jewish maternity hospitals in New York City provide facilities for the birth of three thousand babies annually. The report of the Federation for the Support of Jewish Philanthropic Societies states that all beds are constantly full.

A Scheme for Classification of Delinquency in Children

(Continued from Page 514)

he has not been mentally competent to proceed with his education. He remains stationary in one class and there has been a marked increase in weight for the past few years.

Examination reveals a boy showing findings of endocrine dysfunction in that he shows marked obesity, weighs 192 pounds and is only five feet one-half inch in height. There is underdevelopment of the sex glands. He frequently complains of weakness and of headaches. These headaches are considered to be due to the glandular deficiency present.

Psychological examination reveals a dull normal individual.

The boy has been placed on pituitary extract in a therapeutic attempt to supply him with the deficient substance from this gland. Since treatment was started very late, there has not been any improvement in his condition.

Later reports state that he continues unable to progress further in school; is very lazy, shiftless and apathetic. His headaches, however, have become less frequent following treatment.

Psychotic Group

Case 8.—Boy, age 15 years, was committed to State Home with a charge of breaking, entering, and assault. Mental examination revealed the boy as very listless. He spoke of his serious delinquency in a matter-of-fact fashion; stated he was not sorry for the man he black-jacked. He admitted hearing voices. These voices told him to steal and rob. They said to him: "You live here in misery and there are lots of people with money who won't help you. Why don't you go and get some?" He thought the people talked about him and made fun of him. At times, he felt somebody was controlling his mind and that certain people could make him do anything they wanted. He imagined that several boys could influence him and tell what he was thinking about.

Father has a criminal record and one brother is delinquent. Father deserted home and the family was destitute and poverty stricken. This case showed many psychotic features of schizophrenic type, and for this reason a transfer to the State Hospital was recommended, where the patient could be cared for suitably while he was being further studied.

These cases are cited to illustrate

briefly many of the essentials of the treatment, chiefly of the personality group. To follow our classification, we should indicate measures for adequate treatment of the remaining groups. For instance, the organic group requires careful neuropsychiatric study and observation where specific therapeutic measures could be instituted: for example, the treatment of syphilitic conditions by means of arsenical preparations.

The mental deficiency group requires, first of all, a careful diagnostic study regarding trainability, special abilities and disabilities. Later institutionalization may be indicated with appropriate colonization and parole systems.

The endocrine group may be helped by specific organotherapy as indicated following careful laboratory and metabolic investigations.

The incipient psychopathic group will always require observation in well equipped psychopathic wards. The need for a children's psychopathic ward may be met sometime in the near future in our neuro-psychiatric department. Here we should have all resources of medicine at our command to secure a complete diagnostic survey of the patient such as is offered by thorough physical, therapeutic, x-ray, endocrine, laboratory, biochemical, psychological, and psychopathological studies.

Preventive measures of maladjustment in children with any delinquency will only be possible through thorough publicity concerning the questions involved. Organized neuropsychiatric examination of school children should play an important role in the prevention of delinquency. This would enable us to make a complete study of each individual at the very beginning of their change in conduct when treatment would be most favorable. The institutional care of delinquents has not been referred to, although this constitutes an important part of the scheme for treatment. Our State Homes with vocational reorganization, self-government, and Boy Scout activities certainly should be productive of results. A superintendent of a large state home for boys, informs the author that whereas several years ago, before the above changes were made, one out of two boys paroled was later returned, at present only one out of ten boys paroled returns to the institution.

Public Health campaigns, with the establishment of well equipped court clinics, such as the one we have in Philadelphia; also out-patient clinics and children's observation wards could play a definite part in the winning fight against delinquency and all allied problems such as are presented by mental diseases.

TABLE 1.—DELINQUENCY IN CHILDREN

Types of Delinquency	Preventive Measures and Treatment
Personality Defects Group	Organized Neuropsychiatric examination of school children.
	Re-education of parents regarding child psychopathology.
	Careful habit training—Study of role of situation.
Mental Deficiency Group	Mental Hygiene of the child to be taught in Normal Schools and Colleges.
	Careful diagnoses and early recognition.
	Analytic examination regarding study of: Ability, Disabilities, Trainability. Institutionalization—Colonization—Parole.
Endocrine Group	Appropriate legislation regarding Marriage, Sterilization, etc.
	Early diagnoses and specific Organotherapy.
Organic Group	Preventive medicine.
	Symptomatic and safeguarding therapy.
Psychotic Group	Crusades against syphilis.
	Mental Hygiene. Extension of education to schools and colleges.
	Out-patient Neuropsychiatric clinics.
	Court Clinics to afford early treatment, etc.

We feel that Table 1 constitutes a summary of this question, especially regarding methods for treatment and prevention.

Legislative Measures to Prevent Blindness

The National Committee for the Prevention of Blindness is responsible, according to a recent report, for a diminution in the number of the blind by five thousand during the period from 1910 to 1920. Through the activities of this organization state and local authorities have been interested to concern themselves with protecting the eyes of children in schools, with eliminating certain eye hazards in industry, and particularly with introducing legislative measures to save the 25 per cent of needless blindness attributable to the lack of prophylaxis at birth.

Cool, Comfortable Feet in Good-looking Shoes

TO see them on your feet, is to know they are good looking. To wear them is to know they are cool and comfortable. They are Cantilever Shoes—made with flexible arches that curve up snugly, giving gentle, refreshing support to your feet, harmonizing with the action of the arches and allowing your foot muscles to strengthen through exercise. Cantilever Shoes release hot, swollen feet from the bondage of rigid, uncomfortable footwear.

In Cantilever Shoes you feel cooler because your feet are absolutely unrestrained and circulation is free. Natural lines permit your toes to straighten out and relax. Moderate heels and a snug instep prevent your feet from jamming forward. Soft, light-

weight leathers rest your feet and add to the feeling of buoyancy that comes with foot freedom. You have more energy and a keener relish for pleasure in Cantilevers.

In appearance Cantilever Shoes are trim and pleasing. Their nicely rounded toes, smart walking heels, in a variety of styles, and the fine materials of which they are made are all in keeping with the best dictates of fashion.

Your feet will be free, cool and comfortable for the rest of the Summer if you will go to the nearest Cantilever dealer today and have them fitted to good-looking Cantilever Shoes. At the left there is a partial list of the stores that have been specially selected to sell Cantilever Shoes. If no store in your vicinity is listed, write to the manufacturers, Morse & Burt Co., 15 Carlton Ave., Brooklyn, N. Y. and they will send you the name of a nearby Cantilever store and the new Cantilever booklet.

Cantilever Shoe

Heavy Medicinal Mineral Oil Is Best

THE London Lancet says, "Since the value of a liquid petrolatum (Liquid Paraffin) taken internally is chiefly that of a lubricant, the viscosity of the oil is the important factor. Oils which flow more rapidly are less likely to produce that steadiness of lubrication which is physiologically desirable. They frequently produce intestinal pain and may even escape without lubricating at all. A slow-flowing oil of high viscosity is best."

Stanolind Liquid Paraffin has the unusually high viscosity of 300-310 Saybolt at 37.7 degrees C (100 degrees F); specific gravity of 0.891—0.895 at 15 degrees C (59 degrees F). It is a rich, heavy-bodied, mineral white oil, unexcelled by any of either foreign or domestic origin, for the treatment of intestinal stasis.

Its virtue is two-fold; lubricative and protective. As a lubricant, it facilitates the passage of fecal matter through the abdominal and pelvic colon. As a protective agent, it soothes irritated parts of the intestines and protects denuded surfaces until nature has time to heal them.

The Cripple's Place In Society Through the Ages

(Continued from Page 512)

an evil spirit, the root of our own descriptive word "dwarf." The Romans, among whom theology and its attendant fears and superstitions were at no time fully developed, regarded a human monster, not as the seat of evil but rather as an ill omen, a warning. This is attested by the origin of the word "monster" from "*monere*," to warn, a warning against further or similar transgressions.

Modern Medical Treatment

Throughout the ages we thus note that the cripple was neglected where he was not actually destroyed. A gradual change began to take place during the last century. The number of crippled began to increase, largely through accessions to its ranks of the acquired varieties due to tuberculosis and rickets. Where the mode of living changed from the healthy village life to that of crowded cities the ravages became great. It is estimated that in Germany at present the percentage of deformed is 1.48 per thousand. With such a vast army and the keen struggle for existence something must be done to change them from mere consumers to producers, or from beggars to taxpayers. It was recognized that only through a union of pedagogic and surgical work could an amelioration of this condition be brought about.

München took the lead in this matter in 1832. It established the "Erziehung—Unterrichts und Bildungsanstalt für Krupfelhote Knaaben." In 1884 it became a royal institution. France followed in 1845, England in 1851, then other European countries, and America in 1862. At all of these institutions grade school instruction and manual training are combined. In our country there are three state institutions for crippled children. The Minnesota State Hospital for crippled and deformed children, The Massachusetts Hospital School, and The New York State Hospital for the care of crippled and deformed children. Iowa and Indiana are now supporting progressive institutions.

Orthopedic clinics and hospitals now abound everywhere where the best of care is given the unfortunates, and orthopedics is recognized as a legitimate branch of surgery.

Homes for Cripples

Connecticut.—Newington, Virginia

T. Smith Home, 140 beds; Wilton, St. Elizabeth's House, 30 beds.

Illinois.—West Chicago, County Home for Convalescent Children, 70 beds; Chicago, Home for Destitute Crippled Children, 118 beds.

Maryland.—Orange Grove, St. Gabriel's Home, 50 beds.

Massachusetts.—Hyde Park, New England Peabody Home, 40 beds (educational).

Missouri.—St. Louis, Summer Home for Crippled Children, 20 beds.

New Jersey.—Englewood, Daisy Field's Home and Hospital, 20 beds.

New York.—Garden City, House of St. Giles the Crippled, 64 beds; New York, Darach Home for Crippled Children, 18 beds; Southampton, Home for Crippled Children, 30 beds.

Ohio.—Cleveland, Holy Cross House, 20 beds.

Pennsylvania.—Allentown, Good Shepherd's Home, 56 beds; Philadelphia, House of St. Michael (colored cripples), 37 beds; Pittsburgh, Industrial Home for Crippled Children, 50 beds.

Orthopedic Hospitals

Georgia.—Atlanta, National Surgical Institute, 22 beds; Scottish Rite Hospital for Crippled Children.

Maine.—Portland, Children's Hospital, 52 beds.

Michigan.—Detroit, Michigan Hospital School (educational).

New Jersey.—Orange, New Jersey Orthopedic Hospital and Dispensary, 16 beds.

New York.—New York, New York Orthopedic Hospital and Dispensary, 242 beds; New York Hospital for Deformities and Joint Diseases, 72 beds; Port Jefferson, St. Charles Hospital for Crippled Children, 300 beds; Rockaway Beach, Neponsit Beach Hospital for Children, 120 beds.

Massachusetts.—Boston, Boston Children's Hospital.

Missouri.—St. Louis, St. Louis Children's Hospital.

Ohio.—Elyria, Elyria Memorial Hospital; South Euclid, Rainbow Hospital for Crippled Children, 86 beds.

Pennsylvania.—Philadelphia, Pennsylvania Orthopedic Hospital and School of Mechano-Therapy; Philadelphia Orthopedic Hospital, 136 beds.

Washington.—Seattle, Children's Orthopedic Hospital, 60 beds.

Educational Institutions

Massachusetts.—Canton (state), Massachusetts Hospital School, 300 beds; Hyde Park, New England Home for Crippled Children, 40 beds; Boston, Industrial School.

Michigan.—Detroit, Michigan Hospital School.

New York.—New York Crippled Children's East Side Free School, 120 beds.

Pennsylvania.—Philadelphia, Widener Memorial Industrial Training School for Crippled Children, 112 beds.

Illinois.—Chicago, Spaulding School for Crippled Children, 300.

Miscellaneous Institutions

New York.—Tarrytown, "Robin's Nest," crippled children, 22 beds.

New York.—Society for the Relief of the Ruptured and Crippled, 200 beds.

State Institutions

New York.—West Haverstraw, New York State Hospital for Crippled, 125 beds.

Massachusetts.—Canton, Massachusetts Hospital School, 300 beds. (educational). Now General Children's Hospital.

Minnesota.—St. Paul, State Sanitarium, 230 beds.

Nebraska.—Lincoln, Nebraska Orthopedic Hospital, 100 beds.

Iowa.—Iowa City, 50 beds.

States giving state aid are as follows: Maine, (Portland) 65 beds; Texas, (Galveston) 30 beds; North Dakota, (Fargo), 5 beds; Montana, (Helena), New Jersey, (Newark) 56 beds; Pennsylvania, (Pittsburgh) 25 beds; Michigan, (Detroit); Wisconsin, (Milwaukee); Illinois, (Chicago); and Ohio, (Cleveland).

Mental Capacity of Japanese Children

Prof. Lewis M. Terman and his assistant, Prof. M. L. Darsie, of Stanford University, are making a thorough scientific investigation of the mental, moral and physical characteristics of the Japanese children in California. A preliminary report on the mental condition has already been issued.

According to this report, "the Japanese children were, in general, markedly inferior to American in those tests in which language plays an important part, and equal or superior in tests not of the language type. In tests of reasoning power, apart from language, the Japanese children were equal to Americans, and in tests of rapid learning markedly superior to Americans."

The conclusions reached are:

"The Japanese in California are as a group somewhat inferior in intelligence to northern Europeans, but markedly superior to southern Europeans. In application and capacity to learn, they are probably superior to any European race in America, as well as superior to native Americans. In social-moral traits, they are fully equal, and in many respects probably superior to the average child of other races in California, as judged by their teachers, this statement being true with respect to native American children as well."

"It stimulates peristalsis —and at the same time softens the fecal masses"

That is the conclusion of a noted investigator who recently concluded a series of tests on the effects of Fleischmann's Yeast in constipation.

Authorities have suggested that the increasing prevalence of constipation is due largely to the deficient bulk of many concentrated, artificial modern diets. Where careful dietary regulation proves ineffective, Fleischmann's Yeast offers a valuable supplement.

Recent experiments show that fresh yeast, in quantity of two to three cakes per day, produces by its action a definite increase both in the bulk of the feces, and in their moisture content.

Fleischmann's Yeast is not habit-forming, and may be used without the difficulties attendant upon the use of cathartics and "laxatives." Physicians and hospitals in many

parts of the country are now prescribing it with gratifying results.

Not only does it assist regular intestinal activity, but its vitamin content is highly beneficial, and experiments have shown that it also helps to produce a definite leucocytosis.

Best results are obtained by eating one cake half an hour before each meal, or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk or fruit juices.

A new authoritative book:—written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry and therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing The Fleischmann Company, Dept. Y-22, 701 Washington Street, New York, N.Y.

Home Nursing Care of Paralysis Cripples

(Continued from Page 505)

or is kept under close watch in bed during the first few weeks may mean that the home worker will have to spend months struggling with twisted wrists or ankles, whereas these deformities could have been prevented if proper nursing care had been taught and given while the patient was in the hospital during the acute stages.

Not only the laity but also professionally trained people have failed to recognize the importance of aftercare in this disease. Within the past year we have been asked to give care to several children whose deformities developed while they were in hospitals. One, a thirteen-year-old boy, was kept for six months in a big hospital deservedly famous for the excellence of the work of its attending staff, its interns, and its nurses. This boy was the oldest child of a widowed mother and for this reason was kept by the hospital much longer than any child is kept under ordinary circumstances. When referred to us, his skin was in good condition, his nutrition was fair, but the entirely preventable deformities of his arms, hips, and knees took months of patient, painful effort to reduce. Now he is wearing braces and attending a special school for crippled children and the surgeon in charge hopes that further muscle training and exercise will prevent the necessity of any surgical interference. Time alone will tell. This youngster faces a life of grinding poverty. Already crippled by economic conditions quite beyond his control, the lack of foresight and intelligent observation on the part of the hospital staff (for we can hardly place the blame on any one of the responsible groups) have tremendously increased his chances of an unhappy future. This unintentional neglect has caused preventable suffering, waste of time, the loss of precious schooling and of potential income, for it will be several years before he can even think of securing his working papers and he is the oldest child of a widow.

The first after-care treatment consists of rest in correct or normal position. Fatigue and strain on the affected parts must be avoided at all

costs. Some physicians prescribe this for periods of a year or more. This does not mean absolute immobility in fixed positions or no passive exercises, but patients are encouraged to keep the paralyzed parts in normal position and free from weight or strain by means of simple splints, plaster shells, padding, sandbags, or any device that will not cause unnecessary pain. This treatment hastens the spontaneous recovery of the muscles involved and prevents the over-

should be worked out for it. Needless to say, it is extremely difficult for any nurse, whether or not she has had special training in infantile after-care, to give proper treatment to these children unless they are under the constant supervision of an orthopedic surgeon, although many of the more minute muscle examinations and almost all of the exercises are left for her to work out. And as experience has proved that special training in this work is necessary for nurses, it

is equally true that special orthopedic experience is necessary for the physicians.

Salt baths, very gentle, superficial massage, and external heat, usually applied by means of electric bakers, help to arouse the circulation and tone the muscles for the exercises, which should be graded to the strength shown by the sick muscles. In addition to these exercises—which have to be made into games with very little children but which may be given to older children as one gives gymnastic exercises in the school room—the education of the child and the preparation for his future must be considered. In bad cases, permanent braces for the arms or legs are frequently indicated for months or years. Then the children must be sent to school and it is better for them and their parents if at first they have the advantage of going to a school especially equipped and planned for crippled children. Every crippled child should be treated as if he were a normal member of society; ex-

cuses should not be made for him nor too much unwise pity shown. In a school where every child is handicapped, it is easier to give a crippled child a fair start. Infantile paralysis, fortunately, rarely affects the mentality of the child; consequently, he is almost always able to make his grades in our public schools. But his handicap, whether it consists of a lame arm or leg, makes special training necessary. Occupational therapy is very valuable for our shut-in cases when graded exercises for the hands and arms are necessary, but occupational therapy that is not a true vocational train-

From the first the kind of treatment is emphasized that enables a patient to take care of himself. And positions are prevented which increase or fix deformity.

stretching of the weakened muscles, as well as the resultant contractions of the opposite groups of muscles. A very important part of the treatment is the patient's nutrition. Many of these children have capricious appetites, others are allowed to eat altogether too much, and it is as difficult to work over the emaciated youngster who apparently has no muscles left, as it is to try to teach an overweight child to use crutches or braces properly.

Once the soreness has left the limbs, a thorough muscle examination should be given the entire body to find where the affected part is, and exercises

ing has distinct limitations with children who have possibilities of self-support. In a special school, under the constant supervision of teachers equipped to handle and plan for them, the crippled children have a much better chance to prepare themselves for the struggles of industrial life than in the average public school.

Sickness Means Social Defeat

An attack of acute poliomyelitis has its economic and social side quite as much as its medical and educational. Its cost in the average working man's family is just enough to keep that family hovering on the borderline of poverty for years. Treatments, braces, crutches, sometimes a wheel chair, sometimes a Bradford frame, can best be secured if purchased through a central brace fund. The parents may be permitted and encouraged to pay in installments. An experience of six years has shown us that very few people take dishonest advantage of their loans. Our money comes back to us in small amounts but it comes back steadily.

Far more serious than the expense, however, is the long-drawn-out treatment with its slow, almost imperceptible results. Frequently parents and patients alike lose courage. The temptation to change doctors and to experiment with advertised treatments is a big one and just as we think a child is showing some improvement and is really making progress, we are dismayed to discover that the parents have put the savings of years into an electrical machine or a three hundred down payment to a practitioner who guarantees a cure in almost less time than we can take to think about it. Cases of this sort almost invariably come back to us much the worse for wear.

Not long ago we were asked if something could not be done about a little girl of six who left the hospital with a foot which showed a marked tendency towards serious deformity. The physician at the hospital had recommended the right treatment; the visiting nurse had been at the home before the child was dismissed, explained the care to the mother and secured, as she thought, her interest and help. A fellow-workman, however, had persuaded the father that another doctor knew more than the first. The second doctor recommended a clinic which would have given the child exactly the same treatment that it might have received at the first clinic recommended; but while the family were weighing the merits of these two different clinics in their

minds, a neighbor came in with a flashily-printed advertisement issued by a man who guaranteed to cure almost anything under the sun; consequently these parents, with borrowed money, have taken the little girl to the advertiser and for the time being, have dropped both clinics. The nurse, in speaking of this case, said regretfully: "The trouble is that we shall get that child back in three or four months and it will take us twelve months to straighten out a twisted foot that we could prevent tomorrow if the mother would only trust the child to proper hands." Ignorant people are so tragically credulous one minute; so hopelessly unteachable the next.

Cases like this are not happening as frequently as they were five years ago, which shows that we are making progress; and there is no comparison between the condition of patients who are put under treatment immediately after an attack in 1923, and those who had the disease in 1912, 1915, or 1916, as the case might be. Some time ago we asked several physicians who had been seeing hundreds of these children, what they considered the chief contribution of this home nursing care. Unanimously their answer was that by preventing many deformities, it had reduced the amount of surgical interference that had previously been taken for granted in certain types of infantile cases, and had aroused a very intelligent interest on the part of parents, relatives, teachers, social workers, family physicians, and others which had carried a distinct educational advantage and had furthered the treatment of all crippled children.

As we study the cases from year to year, our failures seem to fall into two groups: (1) Those in which the disease was so virulent that the cells in the spinal cord were entirely destroyed and no nerve-power whatsoever seems to have returned to the weakened muscles; and (2) a somewhat larger group in homes where the parents are too ignorant or too indifferent (or both), to be taught to give the treatments between visits. Lack of home control is just as obvious and just as serious a deterrent to the future welfare of a crippled child as it is in the treatment of a malnutrition child. When rest is prescribed and a child is allowed to scramble around on all fours throughout the day because the mother simply cannot keep him in bed; when a platform splint for a badly paralyzed arm or shoulder is absolutely necessary if the muscles are going to be

saved at all and after one wearing the child decides that he does not like it and will not put it on again, we long for a convalescent home large enough to take all crippled children whose parents are too weak (though neither vicious nor ignorant), to make their children do what is going to be best for their future welfare.

Mothers Save the Day

Our successful cases have been almost entirely in homes where parents—mothers particularly—were eager to do everything that they possibly could for their children. In one family where four children had poliomyelitis at the same time and where the mother had the entire care of a ten-room house with a family of twelve for which to plan, the daily baths and exercises required by two children who were severely paralyzed, were never once neglected. Consequently this family is going to have four self-supporting, and at least three able-bodied, young people a few years hence, whereas under ordinary conditions, with a weak or careless mother, seriously crippled children would have been the inevitable outcome.

Our special orthopedic service costs twice as much per visit as our general work, for the nurses require special training, much more time is spent in clinics, at the brace-makers, and in transportation, and most of the home treatments are long and fatiguing. Nevertheless, we are seeing daily youngsters who have been snatched from a possible life of helpless invalidism and who are being made into potentially self-supporting citizens; consequently we feel that this money has not only been well spent but that it is money put into a piece of research that may have very far-reaching consequences.

The long distances and the lack of better transportation facilities in Chicago have made treatment centers impossible, although in some cities they have been established and the results are good. At the time of writing, four nurses are spending a good part of every morning in four different public schools where there are special rooms for crippled children; one nurse is giving half-time to a treatment center to which the mothers bring their children and at which other patients receive muscle training; and one nurse gives one afternoon a week to a treatment center which, however, is successful only because the Association provides the transportation. Treatment centers are valuable, for they give the pa-

Severe Case of Static Flat Foot

is the cause of inefficiency and much bodily suffering. As a physician you will be interested in learning more about a most successful mode of treatment now used by thousands of successful practitioners in the treatment of weak or flat-foot, Morton's Toe, Metatarsalgia, Hallux Valgus, bunion, painful heel, weak ankles and other conditions where mechanical treatment is indicated.

Dr. Scholl's *Corrective Foot Appliances*

with proper foot-gear and corrective foot exercises usually bring quick relief to these conditions. There is an appliance especially designed for each condition. They are now placed on sale with leading shoe dealers and surgical instrument houses in every city.

Write us name and address of one nearest you and for the new pamphlet, "Foot Weakness and Correction for the Physician," including a chart of corrective foot exercises as recommended by the Medical Department, U. S. A.

NEW YORK

TORONTO

LONDON

KOTEX

Regular Size, 12 for 65c
Hospital Size, 6 for 45c

(Additional thickness)

Kotex cabinets are now being distributed in women's rest rooms everywhere — hotels, office buildings, restaurants, theatres, and other places — from which may be obtained one Kotex with two safety pins, in plain wrapper, for 10 cents.

Comfort

KOTEX are cool in warm weather. They are of lasting softness. Made from Cellucotton and finest white gauze, they bring a new experience in comfort, and quickly become a requisite of milady's toilette. Far superior to makeshifts and other sanitary pads, Kotex have earned the favor of nice women everywhere. It is easy to buy Kotex. They are sold wherever women trade—in drug, drygoods and department stores. It is easy to take a supply in a handbag. Also they are easy to dispose of by following simple directions found in each box, and cheap enough to throw away.

Ask for them by name

Cres, Neenah, Wis.

INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX

tients and the mothers of patients an opportunity to see the improvement or lack of improvement in similar cases. They also save the energy, time, and strength of the physiotherapist or other trained worker. Perhaps our annual Christmas party, which is rapidly becoming a Visiting Nurse Association tradition, takes the place of a treatment center to a very small degree, for every year mothers return with their children and become tremendously interested in youngsters whom they have not seen for twelve months. Frequently these mothers point out to us marked improvement which has come so gradually that we have hardly noticed it. Anything that helps to give the families a standard of comparison is always an asset, whether it is done by means of a Christmas party or by means of classes at a treatment center.

The home nursing care is never wholly a success unless the families want it and are sufficiently interested to learn to give certain treatments fairly well. Medical and nursing care can prevent much but they will never be able to overcome parental inertia or indifference.

Its Application Widens

Work with children who have had infantile paralysis has also taught us that muscle training can be used successfully in all sorts of paralyses, after sprains and fractures, and in almost any kind of pathological loss of function following disease or accident. We are being asked to organize classes for children with spastic paralysis; heart cases who need carefully-graded exercises are being referred to us, and in time, we believe that muscle training will take its proper place in any scheme of corrective gymnastics that is going to be used for sick and convalescent patients. Muscle training is not massage, it is voluntary effort on the part of the patient to perform certain motions and exercises worked out according to the needs of the part affected. It must be given only in selected cases. Muscle training must be a gentle, scientific and persistent re-education of muscles weakened by disease or accident. Indication for it is found in the loss of function; its aim is to restore latent or lost muscle power. It cannot be given by a nurse, a masseuse or a physical education instructor who has not studied the whole subject thoroughly and carefully, for wrongly administered, it can do just as much harm as good. The home-nursing care not only helps to restore this function but the con-

stant supervision, teaching and encouragement to both families and patients round out the work of the physician, the hospital, the dispensary, and the school.

A Nation-Wide Health Examination Campaign

With the slogan "Have a health examination on your birthday," there was launched on July 4th, 1923, a country-wide campaign for health examinations. This campaign is sponsored by the National Health Council, the members being as follows:

Direct members: American Child Health Association, American Public Health Association, American Red Cross, American Social Hygiene Association, American Society for the Control of Cancer, Conference of State and Provincial Health Authorities of North America, Council of Health and Public Instruction of the American Medical Association, National Committee for Mental Hygiene, National Organization for Public Health Nursing, and National Tuberculosis Association.

Associate members.—American Association of Industrial Physicians and Surgeons, National Committee for the Prevention of Blindness, and Women's Foundation for Health.

Conference member.—United States Public Health Service.

This national health examination campaign will extend from July 4, 1923, until July 4, 1924, and during this year an effort will be made to induce at least ten million persons to have health examinations. In order to carry out these plans through the country, state and local committees will be organized. Attractive publicity material such as pamphlets, posters, and a moving picture will be prepared for the use of these local committees. The public will be urged to go to reputable physicians or agencies for their examinations. Forms for the use of the doctors have been prepared by a committee of the American Medical Association, and special forms for children have been developed by the American Child Health Association and forms for women have been prepared by the Women's Foundation for Health. Intensive preliminary publicity by means of newspaper and magazine articles, photographs, and speeches before conventions and meetings is already under way. The campaign will be financed from the national standpoint by contributions of money and services from members of the National Health Council and from outside

sources, while in the states local committees will undertake to raise such funds as may be necessary.

Since it is generally acknowledged by sanitarians that one of the greatest needs in modern preventive medicine is a periodic complete and adequate human inventory, this health examination campaign should prove of the utmost benefit to the hygienic welfare of the country. The earnest co-operation of federal, state and local health officials, the medical profession, voluntary health associations, women's organizations, commercial, semi-commercial and industrial agencies, and, finally, the general public is necessary for an effective campaign.

Tentative Program of American Dietetic Association

The American Dietetic Association will hold its sixth annual meeting at Indianapolis on October 15, 16 and 17, with headquarters at the Hotel Claypool.

With the present development of the science of dietetics throughout the country, there exists the greatest need for well-informed dietitians, keenly alive to the problems of the day. The demand from hospitals, universities, schools, public welfare associations and the commercial field for food experts exceeds the supply.

The program for Indianapolis will cover every phase of applied dietetics. Preliminary plans are as follows:

Monday, Oct. 15.

10:00 a. m. Mrs. Octavia Hall Smillie, president, in the chair.

Section on Administration:

Speakers: Miss Effie Raitt, University of Washington, section chairman.
Miss Ruth Luby, University of Washington.

2:00 p. m. Section on Dietotherapy:

Speakers: Dr. Russell Wilder, Mayo Clinic, Rochester, Minn.
Dr. G. H. A. Clawes, Indianapolis.
Miss Amalia Lautz, dietitian, Peter Bent Brigham Hospital, section chairman.

7:00 p. m. Annual Banquet.

Tuesday, Oct. 16.

10:00 a. m. Section on Education.

Round table discussion: led by Dr. Ruth Wheeler, University of Iowa, section chairman.

8:00 p. m. Speakers: Dr. Louis Burlingham, Barnes Hospital.
Dr. Amy Daniels, University of Iowa.

Wednesday, Oct. 17.

10:00 a. m. Section on Social Service.

Speakers: Mrs. Gertrude Gates Murie, section chairman.
Miss Helen Parsons, University of Wisconsin.

2:00 p. m. Business meeting.

Tea.

8:00 p. m. Address by Miss Lydia Roberts, University of Chicago.

Tuberculosis Among the North American Indians

The report of a committee of the National Tuberculosis Association on Tuberculosis Among the North American Indians has been published as a Senate Committee Print (67th Congress, 4th Session) for the use of the Committee on Indian Affairs. Dr. George M. Kober was chairman of the Association Committee that made the study.

The first part of the report is a historical review of the subject from which the committee concludes that "there is no reason for assuming that the redman is peculiarly disposed to this disease."

"The evidence indicates that in the early days of colonization the prevalence of tuberculosis among the Indians was no greater than among the white race, probably not as great. From the available data it is also evident that there has been a progressive increase in the prevalence of the disease since their contact with the whites."

The percentage of deaths from tuberculosis among the Indians to the total number of deaths was twenty-seven in 1911 and thirty-five in 1915, following which it declined to twenty-seven for the year 1920.

One of the baneful effects of the advent of the white man was the gradual destruction and dispersion of the Indian's game, a condition that made more difficult the struggle for existence and subsistence and caused extreme suffering and semi-starvation. Those familiar with tuberculosis realize the evil effects of poor nourishment coupled with anxiety.

Provisions for the care and treatment of adults in the incipient and advanced stages of tuberculosis is the most urgent need of the Indian medical service. To enable the Commissioner of Indian Affairs to meet the situation properly the report states that two or three sanatoriums for adults are needed, one of them a hospital for hopeless cases. The committee also recommends the employment of additional field for nurses and matrons; increased compensation for all full-time salaried medical officers; and "the continuance of all health activities now inaugurated with the utmost vigor and sympathetic interest and enthusiasm."

The majority of Indians are poor and scattered and their work is often of a temporary character, and the income wholly inadequate to maintain a proper standard of living. Their vitality is often so reduced that they are

unable to do an honest day's work and are cruelly accused of being lazy whereas the great majority are industrious and willing to work when an opportunity is afforded. The committee is convinced that the Bureau of Indians should be entrusted with sufficient funds for immediate relief of distress.

Physical Training in Holland Investigated

The need of economy has led the Dutch to investigate—to inquire into the purpose of teaching and education. "Thus the old question whether the training of the mind must needs be of greater, equal, or less importance than the training of the body comes once more to the foreground," says P. A. Diels in *School Life* for April, 1923.

"Generally speaking," says Mr. Diels, "Dutch physical education is based on the German system of which Gutsmuth was the creator. 'Turnen' was for long years the principal feature, and though our gymnastic unions had no such political aims as the German 'Turnverein,' they enjoyed great popularity among parts of the nation. The other side of physical education, sports and games, was almost neglected; in fact, some twenty or thirty years ago practically no open-air games were practiced in Holland. This has totally changed and for the better, I think; at present every young man or woman has some sport or sports of his own choosing, football being foremost in favor, but a great many practice swimming, boating, cycling, and several ball games, too. Cycling is very popular in Holland owing to the level roads. Of the Amsterdam population of about seven hundred thousand, about one hundred thousand possess bicycles. It is one of the sights of Amsterdam to see the hosts of cyclists running through the streets during the busy hours of the day. Strange to say your baseball is almost unknown in Holland, and the endeavors of some to introduce the game in our country have led to next to nothing."

Interest in physical training is plentiful but funds and teachers are lacking. The Dutch Government appointed a committee to investigate the situation. In the introduction of the committee's report it is stated that it is of eminent importance to the nation that all powers existing in the people—moral, intellectual, and physical—be developed. That is why education must run parallel with mental and moral education. Training must be given to the children in ele-

mentary schools by the common class teacher, while for secondary schools the Danish system is recommended. Special attention is paid in the report to the needs of children between the ages of 13 and 18 years.

Rivalry between the Swedish and German systems animates the present day discussion. Mr. Diels continues, "The advantages of the Swedish system, which are especially found in the analyzed and localized exercises, are not denied, but those in favor of the German-Dutch system assert that the same advantages are found in the more complicated exercises. But the principal argument is found in the fact that the German-Dutch system, with its variety of interesting exercises is exceedingly attractive for the pupils. . . ." The writer also says, "without regard to the system employed, the personality of the teacher plays such a great part in all tuition that both systems can boast of excellent results."

Traveling Milk Laboratory in Indiana

During the summer of 1921 the Indiana State Board of Health adopted a resolution establishing a traveling milk laboratory as a part of the Department of Food and Drugs. Work was begun on November 1, 1921.

Surveys of milk supplies have been undertaken at the request of local city boards of health, chambers of commerce, or interested health and civic associations. The surveys have been made without cost to the cities other than furnishing a room for the laboratory equipped with light, heat, gas, water, and electric current. Transportation was also requested in the earlier surveys but as this proved unsatisfactory in that it could not be depended upon at the time needed, the bacteriologist has been supplied with a Ford coupe.

Seven surveys were completed during the remainder of the fiscal year of 1921 and 1922. These involved several hundred sanitary inspections and the bacteriological examination of 1,018 samples of milk. As a direct result Bedford, Shelbyville, and Anderson have adopted ordinances fixing the standards for milk and milk products and providing for sanitary inspection of dairies and milk plants.

In addition the bacteriologist has carried on educational campaigns in the communities where he worked. More details are contained in the Seventeenth Annual Report of the Indiana State Board of Health for 1922.

Practical Methods for Removal of Dust and Fumes

(Continued from Page 519)

Cowls and induced draft should be installed concentrated near the larger moulds and fresh air supplied six feet from the floor to overcome this.

In handling feathers and other dusty materials, one should use air through machines like Kitson condensers in order that this dust may be confined and removed while being taken from bales and carried to the manufacturing departments. Air handling should always be a means for dust prevention.

arator is the one that gets the fine dust. Straight sided types with extra long cones not less than 50 per cent greater length gives 80 to 90 per cent fine dust removal, that is, dust that will pass a two hundred mesh. The resistance of these collectors runs about one to two inch water.

Situations, then, in which the practical difficulties arise follows:

(1) The dampers or covers at intake of connection to exhausters necessary to give uniform volume

separators of cyclone type.

(6) Sweep-ups are not to be figured in load and area of fans. Automatically closing damper lids are to be provided on each sweep-up, these connections to be not less than five inches in diameter.

Narcotic Education Week in California

The school law of California (1921) reads as follows:

Instruction must be given in all grades of school and in all classes during the entire school course, in manners and morals, and upon the nature of alcohol and narcotics and their effect upon the human system, as determined by science. In all teachers' training classes in the normal schools of this state, adequate time and attention shall be given to instruction in the best methods of teaching the nature of alcohol and narcotics and their effects upon the human system, and all examinations for the granting of certificates to teachers by Boards of Education shall include this subject.

The week beginning May 27, 1923, was observed as Narcotic Education Week in California, during which special emphasis was placed on instruction regarding the nature of narcotics and their evil effects.

The Menace of Morphine, Heroin, and Cocain by Montaville Flowers and H. R. Bonner (Bulletin No. 2, International Narcotic Education Association, May, 1923) was used as the basis of the special instruction given during this week.

A special course, made possible by funds given to Columbia University by John D. Rockefeller, Jr., is being offered to physicians of New York State continuously throughout the summer months and as long thereafter as may be needed having as its object the establishment of facts of importance regarding the dietary treatment of diabetes as well as a comprehensive summary of clinical experience thus far obtained in the use of insulin. A nominal fee is charged and the course is open to active practitioners of medicine who may desire to make immediate clinical use of this information.

New York State service to deserving children is now extended to 125 hospitals and dispensaries in eighty-five different localities throughout the state.

Fig. 2. An elaborate system for dust removal installed in a large hat factory at Danbury, Conn. An extremely dusty process is thus made safe for the workers.

Galvanizing tanks, acid baths, soda kettles, lead baths are easily handled but require proper treatment of hooding. In general, the hood should be larger than the surface of exposed kettle, the velocity 250-300 though the gross area of kettle should be maintained, not depending too much on natural exhaust. Get the hood as low down as possible. Use asphaltum paint or better still Elaterite No. 40 on coating surface, or tiling vitrolized or treated best for certain acids. Use wood, aluminum or acid resisting treated cement for nitric acid fumes. The fans are arranged for chain drive.

Use for sulphurous acid gases, (chloric and hydrochloric acid gases), but never for the nitric, a regulus metal casing and wheel and protected steel shaft. Nicrome steel is used for spider on nitric acid fumes with aluminum floats and side plates on wheel.

The practical dust collector or sep-

through each orifice are omitted. The practice of estimating speed changes from pulley sizes is hazardous. Don't estimate; know.

(2) It is necessary to specify heavy gauge metals in fan wheels and roundabout for handling clay products, grinding separation, and for separating dust from seeds and ores.

(3) It is safe to say that no exhausters should be specified where exhauster efficiencies run less than 50 per cent static efficiency. One exhauster largely used in Chicago for grinding and buffing tests runs 36 per cent maximum efficiency based on static pressure.

(4) Sander machines should be hooded at point of dust emission, the safe rule being to hood liberally both vertical and horizontal sanders.

(5) Fine dust, such as vernier saw and sander operations should pass through cloth screen eliminators unless coarse material is thrown into

Your Patients Are Just As Human

WHAT is it speeds you up in the bath? The thought of the bacon and eggs—or the aroma of rich, steaming Coffee?

And home for lunch after a strenuous morning—what gives more zest to the meal than Coffee?

As to the evening meal—you'd consider it incomplete without the final touch bestowed by Coffee!

Has it hurt you? Has Coffee really harmed you? Of course not, or your balanced judgment would have banished the steaming cup long ago from its welcome place beside your plate—after you had *convinced* yourself that Coffee was to blame for any discomfort—and *only after conviction!*

Your patients are just as

human as you. They like Coffee. It is the preferred beverage of most Americans. Its aroma excites appetite—a most important factor in the management of every case. Its peristaltic action is favorable.

Moreover, "caffeine may slow and steady a weak heart by stimulation of the vagus center, and thus may strengthen the heart," says Dr. Oliver T. Osborne, Professor of Therapeutics at Yale University, in his book on *Therapeutics*. And, further on, "it should be remembered that caffeine is as well administered in the form of strong coffee as in any other."

Why treat your patients other than you yourself would wish to be treated? Why disregard Coffee as a possible therapeutic aid?

Oregon Leads in Rehabilitation of Injured

(Continued from Page 518)

The young man was operated on several times by the surgeons and the operations were highly successful. Between operations he continued with his drawing, more as a means of occupying his mind than for any other purpose, for in the opinion of the vocational director the problem could not be solved unless the surgical department could show satisfactory results. After a time the work of the surgeon was so successful that this man was able to walk with the aid of crutches. He continued with his drawing and made most wonderful progress. He is now living in a family hotel with his room on the second floor. He walks up stairs to his room with the aid of his crutches, downstairs to the dining room, and frequently walks out on to the porch and down on to the side walk in front of the hotel. He has familiarized himself with the building code of the city of Portland and has done some very acceptable work in architectural design and drafting. He has been able to secure a number of jobs in making drawings, specifications, etc., for individuals who were applying for patents. At this time it is thought that within a year or so this man will be able to take a position as a regular draughtsman and will be able to get to and from his work by the aid of his crutches alone.

Back into the Game

It has always been the opinion of the director of Vocational Rehabilitation that the first great problem is that of the injured individual's mental attitude. Each individual is a distinct problem. Some will meet the director in a friendly spirit of cooperation showing a desire on his part to get back into the game. In such a case the problem then hinges upon the man's past experiences as a basis for determining his future occupation. If the man's injury is of such a nature that his past experience will not function in a new occupation, then the problems becomes one of discovering the man's desire for or liking of a particular occupation. As an illustration of this particular phase of the work I am reminded of an individual who had always been a carpenter. He had served an apprenticeship in his native country as a carpenter and

cabinet maker, had come to this country and worked at the trade in cities until he was thirty-four years of age. He had never done any farm work. He was married and had a wife and three splendid boys. The wife had been raised on a farm in Iowa. This man, working in the shipyards as a ship carpenter, lost his right arm at the shoulder. A carpenter without his right arm is about as nearly 100 per cent vocationally handicapped as possible for a workman to be. This particular problem had to be solved on the basis of the future outlook for that family of

Fig. 4.—Training in the Oregon Institute of Technology fitted this man to establish his own automobile repair shop. He employs several men, modernized his shop, is much more prosperous than he has ever been, and, according to his own statement, is happier.

boys. The farm experience of the wife was a determining factor. The man believed that if he could be given some special training in poultry husbandry, vegetable gardening, and dairy husbandry that he could manage a small farm near the City of Portland and make a living for himself and family. He was sent to the Oregon State Agricultural College and there given vocational courses in the above mentioned subjects. After he had finished his training, which covered about eighteen months in school, he was granted a lump sum of 50 per cent of his award, and with this money purchased a small farm of eighteen acres. He is now living on the farm and doing exceptionally well, as he has three cows and a number of chickens, (poultry husbandry being his major occupation). He raises vegetables for the market and has set out a young orchard on a part of his land.

The best results obtained in any occupation that we have tried to fit men for have been in barbering. We have

had five cases where the individuals were entirely incapacitated for their former occupation, but were able to take up the occupation of barbering. They have finished their courses and each of the five is now making good. Three of these own and operate their own shops, two are working in an adjoining state at the regular barber's wage and as four of these men are men having families, they are not only supporting themselves, but their families as well. The fifth one, the unmarried man, owns his shop in a little town in Oregon and is considered one of the progressive business men of that town and will, in the opinion of the writer, soon be elected mayor.

For various reasons poultry husbandry is the favorite agricultural occupation for these industrial accident victims. Figure 3 illustrates what is being done along this line. This man was a carpenter and millwright. A scaffold fell with him, injured his leg permanently, injured his back, also permanently, and a timber from the falling scaffold struck his head. In the opinion of the doctor the head injury was probably the greatest handicap of the three. We experimented with this man for six months. We requested him to take charge of a small flock of baby chicks, about fifty. This was to determine whether the man could follow out a certain line of reasoning or take instruction and keep track of a series of problems involving poultry husbandry. He made wonderful progress and at the end of the experiment was very much interested in the poultry work. We then gave him a correspondence course in poultry husbandry and by close supervision helped him in his various problems. The picture shows him at work on his home farm, where he now has a flock of four hundred laying hens and this spring should start with one thousand baby chicks. Since the first day of September, 1922, his accounts show that he has average fifty-two dollars a month labor cost on his flock of about four hundred laying hens. This means that he has paid for the feed of the hens and received fifty-two dollars a month for his labor in caring for them, and for overhead expense, such as buildings, equipment, etc.

Do you ever question your sterilizing methods?

Every treatment or examination room needs a sterilizer that will prevent chance of infection from unsterile articles. If you did all your work at the Hospital you would never think twice about this danger.

Now you can have that same surety with the use of Castle sterilizers. They are safe because they are made right in every particular—and have been for thirty years. They are a credit to any operator.

"Every patient looks for a sterilizer"

CASTLE

Complete line of Physicians', Dental, Hospital and Bacteriological Sterilizers

WILMOT CASTLE COMPANY, 1153 University Ave., Rochester, N. Y.

No. 1416

This new unit has a 14" instrument sterilizer, 3-gal. water sterilizer, a table top and cabinet. Neither sterilizer can boil dry. Single action lift for cover and instrument-tray. Three way faucet allows sterilization of water in the gauge glass. Even if you have a sterilizer send for catalogue "H".

Those Who Work In Busy Offices

labor under conditions which impose a constant tax on the nervous and mental forces of the body. Extreme fatigue is a natural consequence, but those who wear

O'Sullivan's Heels

have learned that in thus avoiding the nervous tension caused by the harsh impacts of hard leather heels, they can greatly reduce nerve tire and exhaustion, and as a logical result do more and better work.

It is easy to understand, therefore, why so many physicians advise O'Sullivan's Heels for those who work under nerve tiring conditions.

O'SULLIVAN RUBBER CO., Inc., New York City

On account of the many automobiles used in the country there is a demand for auto mechanics. Many of our injured men express a desire to take up the work as general repair men with a view usually of purchasing a garage and going into business for themselves. Figure 4 shows the most successful man that we have trained in this work. This man has a wife and two children. He was trained in the Oregon Institute of Technology as an auto mechanic and rented a garage that had been closed on account of the former owner failing in the business. He took possession of this garage and repair shop on July 4, 1921, and from the very start has made it a paying proposition. When he took it over the equipment was very limited. He has bought and installed modern machinery. He has had the building doubled in size. At one time when the director of Vocational Rehabilitation visited him he had four workmen employed. He now states that he is making more money than he ever made in his life and is happy in his work.

When society has learned that this work of vocational rehabilitation means more than simply returning the individual to a gainful occupation or industry there will be a united effort on the part of all interested to develop this work. The results to be obtained are more far-reaching than that of simply returning this or that individual to a condition of vocational efficiency, for it touches the lives of those near and dear to him. It is not for the purpose of making this or that individual an efficient workman alone, but it is for the purpose of first physically rehabilitating the individual so that he may enjoy the fruit of his labor; that his mother shall have the strength of his arm in her old age; that his wife shall not be an untimely widow; that his children shall have a father; and that cripples and hopeless wrecks who were once strong men shall no longer be a by-product of industry."

Tuberculosis Committee Educates Workers

The Tuberculosis Committees of Shamokin, Pa., recently decided to carry out a health educational program among the workers in the industrial plants in its territory. The committee won the active sympathy and co-operation of both the employers and employees and the work already promises to prove effective in raising the health standards in Shamokin and the surrounding terri-

tory. Miss Verna Hoagland, executive secretary of the Shamokin Tuberculosis Committee is actively in charge of this industrial health work.

Shamokin borough and Coal township, geographically one, have an area of 29.4 square miles and a population of 35,693, containing a large percentage of Polish, Slavish, Lithuanians, Russians, Italians and Pennsylvania Dutch.

There are seven collieries employing over 5,000 men in Shamokin. The other industries are silk and hosiery mills. The committee found there are four silk mills, five hosiery mills, two ice cream plants, two large baking companies, a noodle factory, a pure food products concern manufacturing bouillon cubes, a wash dress factory, an overall factory and a cigar factory.

Members of the Tuberculosis Committee visit many of these plants each month, put up posters, distribute literature, and talk to the employees.

Comfort Temperature for Indoor Workers

Fat men endure high temperatures better than thin men, according to a statement issued by the Carnegie Institute of Technology on the basis of research undertaken by the American Society of Heating and Ventilating Engineers, the U. S. Bureau of Mines, and the Carnegie Institute at Pittsburgh. The object of the research was to determine the "comfort lines" of persons indoors. The subjects were studied first by rest in still air, and then under successively varying conditions.

One of the important results of the experiments was the discovery of the great variations of external temperature which the human being can endure and retain his physiological efficiency. Another facts discovered was that increasing pulse-rate is more the cause of discomfort than is body temperature, when in a heated room.

MENUS FOR A THIN PERSON

These menus are planned to tempt the lagging appetite of a person whose ordinary requirement is 2,000 calories. Each day furnishes about 2,600 calories.

BREAKFAST

Orange Juice— $\frac{1}{2}$ Cupful
Egg—1 Bacon—2 Small Slices
Toast—1 Slice
Butter— $\frac{1}{2}$ Tablespoonful
Coffee au Lait— $\frac{1}{2}$ Cupful Milk, 2 Teaspoonfuls Sugar

MID-MORNING LUNCH

Cocoa—1 Cupful (All Milk), with 2 Tablespoonfuls Lactose Dissolved

LUNCHEON

Creamed Chicken on Toast-points— $\frac{2}{3}$ Cupful
Lettuce and Tomato Salad— $1\frac{1}{2}$ Tablespoonfuls French Dressing
Bread-sticks—3
Prune Whip— $\frac{3}{4}$ Cupful
Sponge-cake—1 Small

AFTERNOON TEA

Nut-bread Sandwiches—2 Lemon Tea
Sugar—2 Lumps

DINNER

Lamb-chop—1 Baked Potato—1 Medium
Creamed Peas— $\frac{1}{2}$ Cupful Peas, $\frac{1}{4}$ Cupful Sauce
Endive Salad— $1\frac{1}{2}$ Tablespoonful French Dressing
Bread—2 Slices
Butter— $\frac{1}{2}$ Tablespoonful
Charlotte Russe with Ladyfingers

BEDTIME

Milk—1 Glassful Ginger Cookie—1

BREAKFAST

Grapefruit— $\frac{1}{2}$ Medium
Cooked Wheat Cereal— $\frac{1}{2}$ Cupful
Thin Cream— $\frac{1}{2}$ Cupful (for Cereal and Coffee)
Sugar—2 Tablespoonfuls (for Grapefruit and Cereal)
Soft-Cooked Egg—1
Toast—2 Slices
Butter—1 Tablespoonful
Coffee
Sugar—2 Teaspoonfuls (for Coffee)

MID-MORNING LUNCH

Milk—1 Glassful

LUNCHEON

Club Sandwich—Large
Cocoa— $\frac{3}{4}$ Cupful
AFTERNOON TEA
Cream-Cheese and Date Sandwiches—2
Tea
Sugar—2 Lumps

DINNER

Clear Soup— $\frac{1}{2}$ Cupful
Beefsteak—Large Serving
Potato—1 Medium
Scalloped Cabbage— $\frac{3}{4}$ Cupful
Bread—2 Slices
Butter—1 Tablespoonful
Ice Cream— $\frac{1}{2}$ Cupful
Coffee

BREAKFAST

Orange—1 Medium
Oatmeal with Dates— $\frac{1}{2}$ Cupful Cooked
Oatmeal, 4 Dates
Thin Cream— $\frac{1}{2}$ Cupful (for Coffee and Cereal)
Corn-meal Muffins—2
Butter—1 Tablespoonful
Coffee
Sugar—2 Teaspoonfuls

LUNCHEON

Corn a la Southern—1 Cupful
Roll—1 Butter— $\frac{1}{2}$ Tablespoonful
Lettuce Salad with French Dressing
 $\frac{1}{2}$ Tablespoonful Dressing
Frosted Cup-Cake—1
Cocoa (All Milk)— $\frac{3}{4}$ Cupful

DINNER

Baked Ham—Large Serving
Spinach with Egg—1 Cupful
Scalloped Potatoes—1 Cupful
Bread—2 Slices
Butter—1 Tablespoonful
Baked Apple with Whipped Cream—Large Apple
2 Tablespoonfuls Cream
2 Tablespoonfuls Sugar

BEDTIME

Malted Milk—1 Cupful, and
1 Tablespoonful Lactose Dissolved

victims, as was developed, were not only ignorant of the etiology of this destructive and incapacitating disease, but were also devoid of any knowledge for preventing its dissemination. An urgent requisite, therefore, is comprehensive instruction by the reservation physician regarding the individual victim's care of his eyes and methods of destruction of the pathological secre-

in their native environment is due principally to medical negligence and educational neglect.

The writer wishes to express his deep appreciation of the generosity of Harmon W. Hendricks, Esq., the trustee of the Museum and patron of the Hendricks-Hodge expedition, who made possible the studies on which this brief paper is based, and to ex-

Well poised, muscularly well developed, with readily visible ribs and relatively prominent joints, these men show great agility and nervous endurance. The muscles of the feet and legs are not nearly so large as one would expect in a people who run as much as the Zunis do.

tions. That such instruction would be practicable, would be acceptable, and would probably go far toward preventing this disease, the writer has not the slightest doubt, for in his short residence among these people he found them not only willing but actually eager to cooperate in any measure which offered benefit. Response to a few applications of a weak solution of silver nitrate was so pronounced in the cases of trachoma which came under the writer's observation that he is firmly convinced that much suffering will be ameliorated and loss of sight from this cause prevented if conscientious, methodical, medical attention could be procured for these government wards.

In conclusion, the writer feels justified in stating it to be his belief that the prevalence of pestilence and insanitation among the Zuni Indians

tend his thanks to Mr. F. W. Hodge in charge of the field work of the expedition, whose knowledge of the Zunis and his congenial relations with them greatly facilitated these observations.

A study of summer camps in the United States was begun in June by the Playground and Recreation Association of America under the supervision of an advisory committee headed by Dr. J. H. McCurdy. The study is under the immediate direction of L. H. Weir, an expert on camps and municipal recreation, and will include the preparation of a practical summer camp book.

The Playground and Recreation Association 1923 Congress is announced to be held at Springfield, Ill., October 8 to 12.

4 MONTHS' RESULTS

A Springfield (Mass.) woman suffered from flat feet and bunions caused by wearing narrow-toed shoes. A local doctor advised her to wear

GROUND GRIPPER WALKING SHOES

She did, and he kept careful diagrams of her feet from April 19th to July 10th. The above drawings are reproduced from his records. They speak for themselves.

"GROUND GRIPPERS" are the ORIGINAL muscle-developing health shoes for Men, Women and Children. They are universally recommended by physicians and surgeons. Instead of imprisoning arches and toes, they flex naturally with your feet in every part—at every step. Nerve pressure is relieved—stagnant circulation quickened—weak muscles strengthened—painful swellings reduced—deformed bones straightened. Feet are completely restored to normal shape, vigor and comfort. And these results are permanent.

"GROUND GRIPPERS" are imitated but never duplicated

Its Parallel Rays Penetrate Deeply

Searchlights have parallel rays because they penetrate space better than divergent rays. They also penetrate further into any translucent medium such as tissue.

The Thermolite has a highly polished parabolic reflector that provides a parallel beam of light having maximum penetration with minimum current consumption. Practically all of the heat generated is utilized for treatment and not for overheating the apparatus.

There is no focal spot to burn or blister. Nevertheless there is more than sufficient evenly diffused heat for bodily application derived from comparatively small light sources.

Radiant Light and Heat is much more efficient and convenient than ordinary applications which heat by convection.

A trial of

Thermolite Radiant Light and Heat Applicator

will convince the most skeptical physician of its merits.

Thermolite is scientifically designed and well made. It is in use in Government hospitals and in the clinics of such industrial organizations as Standard Oil Company, Carnegie Steel Co., Pittsburgh, Crucible Steel Co., Harrison, N. J., Walter Baker Co., Thos. G. Plant Shoe Co., Boston, Mass., Aetna Life Insurance Co., and in private practice for treating

Colds Lumbago
Eczema Neuritis
Rheumatism Sprains
Female Complaints Erysipelas

Genuine Thermolites are branded—Look for the name on top of applicator. It is your guarantee of satisfaction.

No. 0670—Office Applicator
Reflector 12" diam. Stand adjustable from 57" to 96" high. Consumes 375 watts at 120 volts A.C. or D.C. Covers 300 square inches 36" from reflector. Finish, Olive and Nickel. Price complete with stand \$30.00 each.

No. 0645—Hand Applicator
Same design as 0670 only 8" diam. Consumes 200 watts, 120 volts A.C. or D.C. Made of Aluminum, weight 16 oz. Finish Black and Nickel. Price complete without stand \$10.00 each. Folding stand only for No. 0645, \$6.00 each.

Sewage Disposal in City of Brockton

(Continued from Page 516)

the particular type of screen which had been used cost about eight thousand dollars annually, and it was estimated that the sedimentation tank would cost about five hundred dollars. Neither of these figures includes overhead charges, but they are the actual amounts to be expended by the city each year, exclusive of interest on bonded debt. It may readily be figured from the above that plain sedimentation was by far the cheaper, and as it had demonstrated its merits whereas a screen located at the flow line of the sewage would still be an experiment, the former was adopted.

Intermittent sand filtration in the earlier days of the plant had produced an effluent that was highly purified, and there is no reason today why it would not still give excellent results if the dose of sewage was no greater than an average of 40,000 gallons per acre per day. The present average flow is more than 3,400,000 gallons daily, with a maximum as high as 5,000,000 gallons. The latter will probably be the average figure by 1935. At the time of construction of the new disposal works—1919, 1920, 1921—it was estimated that forty-four new acres of sand would be required to give proper purification. The land for this purpose was not available within the city limits. The legislature, as already stated, had previously refused the city the right to acquire land in Easton, and it probably would have been impossible to gain their sanction in 1919. A plant of over eighty acres of sand, however, would have been so large as to be unwieldy. The construction cost of the addition was estimated at \$220,000.

Activated sludge as the main method of disposal was not seriously considered, partly because of the sludge problem but more so because it was very doubtful that the state department of health would grant its approval. For the latter reason a thorough study of the sludge problem was not made. Experiments with deeper trickling filters than the one originally built, with plain sedimentation as a preliminary process, proved that this method of purification would give satisfaction. An average depth of stone of nine and one-half feet seemed to give the best results, and it appeared that the bed could be dosed at the rate of one and three-quarters million gallons per acre per day. The construction cost of in-

creasing the depth of the existing one-half acre three feet and building one and one-half acres additional was about \$250,000. The original cost of the stone plant was, therefore, very little higher than the cost of sand would have been, and at the same time a much more compact plant is obtained. The maintenance cost was the final analysis, and at that point there is no comparison. The labor cost of maintenance of the trickling filter, which is the entire cost of either plant, as plenty of sand for the replacement of the surface of sand beds is available, is about \$2.50 per million gallons, while that of the sand beds is over four times as much.

There was, then, little difficulty in making a choice of disposal works for the city. Plain sedimentation and trickling filters have been built to be used in conjunction with an excellent sand plant, and sufficient area is now available and will be available for the next few years to purify the very concentrated sewage of the city of Brockton to the same high degree that the original sand plant did two decades ago, when the population was about 40,000 and the daily average flow was less than 800,000 gallons.

Filipino Youth Thrive on Physical Education

Physical training has made the Filipino schoolboy of today far superior to the boy of twenty years ago, states the annual report of the Filipino director of education. It has taught the native pride in his physical well-being, sportsmanship, team work, and self control.

From thirty to forty minutes are devoted daily in elementary schools to physical training, comprising marching, calisthenics, group athletics, games, and dancing. Sixty minutes a day are spent by boys in secondary schools in military drill, group athletics and impromptu games, while girls in Filipino secondary schools spend sixty minutes three days a week in marching, games and similar activities.

Most of the schools are community centers, the most effective probably being the Central Luzon Agricultural school located in the midst of one of the largest rice producing regions. Physical education has given the youth of the Islands training in community leadership and a new national solidarity, the report states.

Great Britain Notes Decrease in Compensation Cases

The report just issued by the British Home Office covering distribution of compensation funds for 1921 indicates larger awards, for limited periods, than were provided for by the original act. The report notes a striking growth in the number of cases of miner's nystagmus since 1908, the first full year after the disease was scheduled under the act. The number of new cases advanced from 386 in 1908 to 1,375 in 1911, 2,775 in 1914, 2,865 in 1920, falling off to 1,913 in 1921. The aggregate number of cases, that is, those continuing from previous years, has shown an unbroken increase, reaching the maximum of 4,804 in 1921.

Statistics are presented for the seven great groups of industries in which returns are called for from employers under a section of the act. These are mines, quarries, railways, factories, docks, constructional work, and shipping. While these groups cover a large proportion of the chief industries, they do not by any means, the report emphasizes, cover the whole field. The act applies to commercial, clerical, and domestic employments, besides the industries of building, road transport, and agriculture, which are not embraced in the figures given.

The reports in the seven groups named covered 146,946 employers, of whom 120,846 were included in mutual associations and insurance companies which made the returns for the employers included in or insured by them. These returns covered 70.2 per cent of the fatal cases and 69.3 per cent of the compensation in such cases; also 72.4 per cent of the disability cases and 75.2 per cent of the disability compensation. Of the total amount of compensation, £2,480,005 (\$12,068,944, par), or 45 per cent was paid by mutual associations; £1,632,405 (\$7,944,049, par), or 30 per cent, by insurance companies, and £1,396,985 (\$6,798,428, par), or 25 per cent by uninsured employers. Separate returns from employers numbered 26,000, of which 23,810 showed no cases of compensation under the act.

The number of persons under the act in the seventh industries was 7,315,866, a reduction of a little more than 1,000,000 from 1920. Fatal cases during the year numbered 2,385—more than 1,100 less than in 1920; while non-fatal cases showed a falling off of more than 98,000, being 283,361 in 1921 as against 381,986 in the preceding year. Payments for compensa-

tion in fatal cases totaled £518,064 (\$2,521,158, par) or an average of £217 (\$1,056, par) per case. The payments in non-fatal cases totaled £4,991,331 (\$24,290,312, par).

The falling off in the number of accidents in 1921 is explained by the increase of employment, while in the reduction in wages which took place in many important industries is also described as influential. However, the report points out, the total amount of compensation paid in non-fatal cases is by no means commensurate with the fall in the number of cases. The number was reduced by 25.8 per cent while the amount of compensation was but 4.4 per cent less. Lump sum settlements in 1921 averaged £73 (\$355 par), as against £62 (\$302) in 1920, while the average amount in weekly payment cases advanced from £11 (\$54) in 1920 to £13 (\$63) in 1921. This increase is attributed to the depression in trade and consequent lack of employment, which delayed the return to work of disabled workmen either at full employment or at light tasks.

Industrial disease cases, the report shows, occurred mainly in the mining industry, chiefly due to nystagmus, heat hand, and heat knee.

Good Proportions in the Diet

Good Proportions in the Diet by Caroline L. Hunt (U. S. Dept of Agriculture, Farmers Bull. No. 1313, March, 1923) deals with the problems of food selection in regard to adequacy, wholesomeness, attractiveness, and cost.

Food materials are classified into five groups which bring together under one head those foods which serve some, at least, of the same purposes in the diet, and which can, therefore, be reasonably compared in price. "The amount of nourishment or of material other than water and inedible substances in a pound of each of the different foods is stated in two ways, by weight and by hundred-calorie portions. By means of either of these two methods of measuring food values the amount of nourishment obtained for a given sum of money in buying different foods at different market prices can be estimated and compared."

The Public Health Council of Maine at its meeting June 22 voted to establish a division of dental hygiene, voting five thousand dollars of the 1923-24 appropriation to be used for the purpose.

Am I Physically Fit to Teach?

To Determine Whether School Assignments Carry Too Great a Physical Strain, Watch the Weight Record Charts, says Professor Clark

BY MRS. ERNEST R. GRANT, DIRECTOR, CHILDREN'S HEALTH CRUSADE, WASHINGTON, D. C.

AM I physically fit to teach? Will I pass my physical examination? These are questions of importance to every graduate of the normal schools of the District of Columbia. Before graduation all student teachers are required to undergo an examination to determine their physical fitness to engage in the teaching profession, and all remediable physical defects found must be corrected before their appointment is confirmed. Applicants having serious permanent defects are rejected. This examination, and the fulfillment of its requirements, is extended to include all others applying for teaching positions who are not graduates of the local schools. The examination is made by the school medical inspection force.

One of the greatest single factors in preparing the student teacher to pass this examination is the intensive health education methods of the nutrition classes that became a part of the regular curriculum of Miner Normal School three years ago. Upon admission to the school each student is given a thorough physical examination, weighed, measured, instructed in keeping the individual weight record

charts, and work is begun toward physical fitness. Each week thereafter the pupils are weighed, gains or losses recorded, and instruction upon the importance of the strict observance of fundamental health practices is given by the assistant director of

minute per week physical training period which was formerly devoted entirely to practical gymnastics. It is in these weekly nutrition class meetings that pupils are brought to some realization of the effect upon health of late hours, insufficient rest, over-fatigue, badly balanced diet, and physical defects. Emphasis is placed upon the fact that regulation of rest, sleep, good health, and good food habits are all matters of education. When these simple practices are violated, reserve energy is destroyed and resistance is lowered. On the contrary, observance of these habits and the correction of remediable physical defects develop a state of nutrition that builds resistance to disease, creates energy, and makes for general well being. There is nothing new in this simple health preaching. But the need of health for good work is so great that if results are to be obtained the subject must be presented in a

manner that will arouse interest. The weight record, with its weekly charting of fluctuating weights, and the recording of factors affecting the physical condition, has proved to be an effective method in stimulating

Dr. Hugh S. Cumming, surgeon general, U. S. Public Health Service, inaugurating the weighing and measuring of five thousand school children, conducted by the local tuberculosis association for the purpose of determining the percentage of underweight in the District of Columbia. Miss Coleman, school nurse, and Dr. Joseph A. Murphy, chief medical inspector.

physical training, Miss Anita Turner. The school physician and various members of the faculty frequently supplement Miss Turner in giving these health talks. The time allotted to the work is taken from the ninety

this much desired interest.

One ambitious pupil—E.—entered the normal school weighing 122 pounds, which was four pounds above normal. She immediately began to lose weight, dropping rapidly to 106. An examination by the school physician did not show a physical cause for this rapid loss of weight. The nutrition worker then took up the question of social environment that is always an important factor in health conditions. The cause was found: late hours

and insufficient rest. E. was working from 4:30 to 10:30 p. m. in a physician's office to assist in the support of an aged mother. She was immediately referred for rest cot periods and in ten weeks had increased her weight 12.5 pounds, which enabled her to carry the full school program and the burden of her family responsibilities without undue fatigue. E. was only one of eight seriously underweight girls all of whom were employed long hours after school, who were recommended for these rest cot periods. Two of the girls were working from 3:30 to 11:30 p. m., in the Bureau of Printing and Engraving, where the type of work they did required them to stand. In each case of these employed girls the rest cot period marked the beginning of a gradual consistent increase in weight. This demonstration was of value to the entire school. Through the cooperation of the local tuberculosis association the cots had been procured, and placed on the roof garden of the school. The time assigned to the girls for the use of these cots came from various free periods and during the regular physical training class.

The effect of an inadequate breakfast or insufficient or badly balanced diet registered to a surprising degree on the weight charts. As a result of this disclosure two changes of general importance to all student teachers took place: the installation of a fifteen minute morning recess period offering an opportunity to purchase milk and graham crackers which were sold at cost; and a hot nourishing noon-day lunch. This service is under the direction of

A group of Miner Normal School students eagerly awaiting the weekly verdict of the scale.

the principal and menus are prepared by the dietitian.

Faculty Meetings

One extension of the nutrition class work is the meetings of the faculty for the specific purpose of discussing the daily program of the underweight student to determine the amount of work necessary for the preparation of outside assignments. An interesting development of these meetings was the discovery that many teachers in their interest and enthusiasm to develop their own subjects were giving assignments for home study far out of proportion to the time allotment in the regular day's schedule. The establishment of a program of home study was introduced that considered not only the results to be obtained in a particular subject but also in the physical well-being of the student. "The greatest single factor in helping us to determine whether a student is working under too great a physical

strain, necessitating the readjustment of home assignments, is the weight record charts," says Mr. E. A. Clark, principal of the school. "They have been instrumental in bringing to the attention of the faculty the necessity of arriving at the point where these adjustments are made; and in gaining the support of the teachers who are thinking more about the physical welfare of the student teacher than of the development of their own particular subject." The attitude

of these teachers is reflected constantly in the fact that reports concerning the physical condition of students come as frequently from the teacher of arithmetic, history or literature as from the nutrition director.

This explains the successful progress of the health education work of the school, which can only exist where there is the closest co-operation of all departments of instruction. Considerable credit for stimulating this interest is given to a small nutrition class of practice pupils directed by the local tuberculosis association three years ago. At that time this class and one for white children were conducted as a demonstration for the further consideration and approval of the Board of Education and the Superintendent of Public Schools. In the opinion of these officials the work justified an extension and the following year sixteen classes were organized, eleven for white and five for colored children, under the joint auspices of the Health

Department, the Medical Inspection Department of Public Schools, and the local Tuberculosis Association. During the current year twenty classes are in operation under the same supervision—sixteen continuing in the public schools, two at the Children's Hospital, and two at the office of the Tuberculosis Association. The personnel of the nutrition class department is composed of school physicians, nurses, nutrition workers and a director. Each class averages an enrollment of twenty pupils. The meetings are held weekly, during school hours. Parents are requested and expected to be—Continued on page 654

Heitmiller, school physician, is in charge of this special class, and Miss Bertha Walker is school nurse.

The Possibilities of a Market as a Service Institution

Even Though It Sacrifice the Picturesque, Sanitation Is a Good Business Asset to Any Market

By CAROLINE B. SHERMAN, MARKET TECHNOLOGIST, U. S. DEPARTMENT OF AGRICULTURE, WASHINGTON, D. C.

SANITATION is an outstanding consideration in the success of public markets from the viewpoint of service to the community. A public market may offer a good outlet for the produce of neighboring farmers, it may offer a good variety of fresh foods to city customers at fair prices, but if the foods and the conditions surrounding their purchase and sale are not properly protected by sanitary measures the market is not living up to its possibilities as a service institution.

That those responsible for public markets are awakening to this fact and are making effective efforts to reach a satisfactory state in sanitary matters is increasingly evident.

Improvements in sanitation can be made without the expenditure of money but this is true only to a limited extent. Many improvements in many markets were necessarily postponed during the war, but during the past two years many cities have taken up the matter of new buildings, extension of buildings or renovation and improvement. The United States Department of Agriculture is receiving constant requests for advice on all of these matters.

Wheeling, W. Va., recently replaced an old market established in 1828 by a new building costing about one hundred and sixty thousand dollars. Detroit has just completed improvements in its eastern municipal farmers' market, the largest in that city, at a cost of \$175,000. Especial atten-

tion was given to sanitation in its improvements, including new service buildings and an incinerator. These improvements were planned some years ago but were postponed by the war. Newark is now building a new market reported to represent an investment of about five million dollars, which aims to be the last word in sanitary equipment and arrangement.

To many it seems unfortunate that strict sanitation discourages the pic-

ture market as a service institution. It is difficult to regulate in sanitary matters, deal with a single product not readily contaminated. The street market at Lindsay, Oklahoma, where farmers' wagons congregate in the streets, on busy days, filling them literally from curb to curb, is devoted solely to the sale of broom corn. In the street markets of St. Joseph and Benton Harbor, Mich., the farmers offer nothing but grapes. But in most street markets the offerings are

many and varied and the trade is with retail customers, usually household providers.

Sanitary regulations for public markets should take into consideration existing state and city laws and ordinances. Some of the existing ordinances may relate specifically to public markets and may govern, rather rigidly, such measures as display of foods, use of screens and accumulation and disposal of refuse.

Regulations for curb markets, larger open public markets, and

inclosed market buildings, naturally vary considerably. For a large market sanitary regulations should cover (1) Condition of product offered for sale; (2) periodical cleaning of containers, counters, stalls and equipment; (3) type and care of garbage can and disposal of garbage by each standholder; (4) conduct of employees, and (5) exclusion of live animals and undesirable persons from the market.

Not only meats and fish in unwholesome condition but all other food prod-

A fruit market planned so that the picturesque and colorful display of wares in no way infringes upon sanitary requirements.

turesque and colorful quality often found in public markets especially in the regions where negroes and small immigrant farmers bring their wares to the market. There were those among the city's visitors who regretted to see the famous old French market of New Orleans put in screens, plumbing, and modern regulations several years ago but the housewives who bought the daily food for their families there, pronounced it an unmitigated blessing. Fortunately some of our open street markets, that would

A southern curb market on a spring morning. Regulations for curb markets, though comparatively simple, are no less important than in the conduct of inclosed markets.

ucts should be regulated. Excessively decayed and offensive fruits and vegetables should be excluded and any other products no longer fit for food.

The stalls, counters, trays, and containers on which foods are displayed or sold must be kept in clean and attractive condition and protected insofar as possible from dust and flies. All stands must be cleaned inside and out, and all equipment must be cleaned at the end of each business day. This cleaning must include the smallest articles of equipment as racks, hooks, and meat saws. Regulations should specify all of these points.

Sanitary conduct of standholders and employees include wearing of white coats, apron or jumper, keeping clothes and person clean, and excluding expectoration and smoking while in the market building. Persons afflicted with any contagious or communicable disease should not be employed.

Next in importance to good sanitary regulations is adequate enforcement. Many an insanitary market now in operation could improve matters greatly without much expense by enforcing the regulations already on the books. Regulations are more readily enforced in inclosed markets but the simpler regulations usually provided for open markets should be strictly carried out.

One of the most noteworthy results of the Federal administration of Center Market in the City of Washington, during the past year, is the demonstration of what can be done in the way of rejuvenation of old markets in sanitary matters. The present building dates back to 1872, and replaced one much older, on Government ground. The market is one of the largest retail markets in the

United States. It has played an important part in feeding the National Capitol and has been patronized by housewives of all classes from all over town for several generations. But it was not in a satisfactory sanitary condition when the Government terminated its lease last year and placed the market under the control of the Secretary of Agriculture.

New rules and regulations were promulgated and have been strictly enforced by the new superintendent, C. W. Kitchen, in so far as present equipment permits. Stands are rented under yearly leases which provide for cancellation upon violation of the regulations. More than seven thousand dollars has been spent in painting the

interior. Public comfort stations and rest rooms were rebuilt at a cost of \$5,000, and many other improvements were made to the property and equipment. Yet the property has earned, during the year, for the United States Treasury, about sixty thousand dollars in excess of expenditures. The initial cost to the Government was \$960,250.

An experienced meat inspector has been employed by the market to devote all of his time to it. So far as known, this is the only meat inspector exclusively employed by a retail market in the country. This inspector is empowered to tag any piece of market or stall equipment that he finds in unsatisfactory condition. "U. S. Insanitary." A tool so marked cannot be put back in use until it has been cleaned, and the tag can be removed only by the inspector or the superintendent of the market.

Improvements in market equipment have largely taken the form of especially-designed sanitary market stands embodying many original features. The first erected has served as a demonstration of a new type of sanitary equipment for displaying fish. The general construction of this 18-foot counter is of hollow tile, reinforced cement, with a glazed tile front, and a vitreous tile base. A marble ledge on the top accepts the framework for the plateglass top and front and nickel-plated glass supports. The counter is divided into four sections. A—(Continued on page 657)

The Antiscorbutic Vitamin and Its Dual Role in Nutrition*

Vitamin C Not Only Serves to Prevent Scurvy, But Its Presence in Sufficient Amount Is Necessary If the Tissues Are to Resist the Onset of Infections

BY G. MARSHALL FINDLAY, M. D., ROYAL COLLEGE OF PHYSICIANS LABORATORY, EDINBURGH, SCOTLAND.

DURING the past few years the intensive study which has been devoted to the subject of nutrition has revealed the fact that certain, by no means uncommon diseases are caused not by bacteria or toxins but by the deficiency of certain essential substances—the vitamins—in the food. Among these deficiency diseases, as they are termed, are beriberi, xerophthalmia—an inflammatory condition of the eye, and scurvy.

Scurvy has been known for many centuries as a malady which inevitably occurs on long sea voyages or during wars when fresh food is unobtainable. One of the earliest accounts of the disease is to be found in the chronicles of de Johnville, who in the thirteenth century took part in the crusades of St. Louis of France, in Egypt. In the recent war there were severe outbreaks in the Balkans, more especially among the Serbian troops and, during the siege of Kut in Mesopotamia, among the British troops. In the seventeenth and eighteenth centuries scurvy played havoc with the personnel of the British Navy, but it was finally stamped out by compulsory addition of lime juice to the ration.

The exact cause of scurvy was for long unknown. It was thought that it might be due to toxins contained in decaying meat or to bacterial infection. In 1895, Theobald Smith had found that when guinea-pigs were fed on a diet entirely lacking in green food they developed a disease characterized by numerous hemorrhages. It

was only in 1907, that Holst and Froelich showed that this hemorrhagic condition in the guinea-pig was identical with scurvy in man and that its onset could be effectively prevented

known both in regard to its properties and distribution in a large number of natural foodstuffs. When cabbage is heated for sixty minutes in the presence of air at a temperature

Vitamin C and the Body Defenses

FROM four to six months on a scorbutic diet suffices to produce a disease picture easy of recognition and violent enough to provoke the necessary precautions to avoid.

Dietaries, however, in which vitamin C is insufficient but not lacking, produce a sub-acute condition of scurvy that is obscure, but of such serious import as to lower the tone and heighten susceptibility to infection of the whole population.

The public, ever slow to correct physical disorders through change of personal habit, even now does not accept that a disease so serious can be cured by so simple a means, and only the findings of the biologic laboratory have served to question methods of cooking, preserving, and storing that may have a bad effect on the unstable vitamin C.

by the addition of cabbage or orange juice to the diet of oats and bran. The antiscorbutic property of such food stuffs as the cabbage and orange is now recognized to be due to the fact that they contain a definite substance, capable of acting in very small quantities and known as the antiscorbutic vitamin, or vitamin C.

Destroyed by Oxidation

Although the exact chemical constitution of vitamin C has not yet been determined, a great deal is

of 80 degrees to 100 degrees C. 90 per cent of its antiscorbutic value is lost, but this destruction is not so much due to the actual effect of the high temperature as to the increased rate of oxidation. If the air is replaced by an atmosphere of carbon dioxide or nitrogen there is then no loss of antiscorbutic power. Ozone and hydrogen peroxide rapidly destroy the vitamin, a point of some practical importance since at one time it was proposed to use hydrogen peroxide for the sterilization of milk. Vitamin C is readily soluble in water, but, unlike vitamin B, it cannot be absorbed from solutions by substances such as fuller's earth or animal charcoal. It is more rapidly destroyed by alkalis than by acids.

Luckily, vitamin C has a comparatively wide distribution in nature. It is present in largest amount in the juices of the orange and lemon and, to a much smaller degree, in that of the lime. The preserved lime juice which was formerly carried on almost all ships had little or no antiscorbutic property. The original "lime juice" which was so efficacious in stamping out scurvy in the British Navy in the eighteenth century was in reality obtained from the lemon which on the shores of the Mediterranean was popularly known as the lime. Later, the juice of the true lime was obtained from the West Indies under the misapprehension that it was identical with that obtained from the Mediterranean littoral. Scurvy,

*The second of a series of articles on the Vitamins. The first on vitamin B by Cowgill, of Yale University, appeared in the August issue of THE NATION'S HEALTH.

however, did not again break out in epidemic form in the navy owing to the more rapid voyages and the generally improved methods of storing food on board ship.

Vitamin C is present also in cabbages, lettuce, watercress, and in a variety of fruits such as strawberries, raspberries, bananas, apples, and especially tomatoes. It is not found in dried peas or other legumes, but if the seeds are allowed to germinate it is then found to be present in considerable quantities, having been formed during the process of germination. Fresh meat contains the antiscorbutic factor in considerable amount, a fact proved by numerous arctic explorers who have kept free from scurvy by eating fresh seal meat. Vitamin C is also present in milk, but the amount in milk is directly proportional to that in the food of the mother. Thus, during the summer and autumn, cow's milk contains much more vitamin C than during the winter and spring when green food is difficult to obtain in large quantities.

Tinned meat and tinned fruit are entirely lacking in this vitamin, while in many of the commercial vitamin preparations it is extremely deficient.

Experimental Scurvy

Scurvy has now been produced experimentally in guinea-pigs, pigs, and monkeys. It is curious, however, that certain animals such as the rat and rabbit do not develop scurvy when vitamin C is entirely lacking in the diet. In the case of the rat, however, small doses of orange juice do appear to improve the general nutrition of the animal, while experiments have shown that even after many weeks on a diet quite devoid of vitamin C the liver of the rat contains a considerable amount of the vitamin. How the vitamin comes to be stored up in the rat's liver is unknown, though the possibility of synthesis is one which must naturally be kept in mind.

The nutrition of the rabbit also appears to be benefited by the addition of vitamin C to its diet. If a pregnant rabbit be fed on a diet lacking the antiscorbutic vitamin, it is found that, though the mother does not exhibit any actual signs of ill health, the young are generally born dead and on microscopic examination show signs of hemorrhage into the muscles round the knee joint.

In a guinea-pig fed on a diet entirely deficient in vitamin C symptoms of scurvy begin to appear after some twelve to fourteen days, while the animal dies with all the

acute symptoms of the disease in from four to five weeks. If, however, very small quantities of an antiscorbutic, such as orange juice, are given to the guinea-pig every third or fourth day, the animal develops a condition of chronic scurvy characterized by no very definite symptoms except slight lethargy and a failure to put on weight.

Latent Scurvy Common

In man, apart from the epidemics which accompany war and famine, scurvy is most commonly seen in young children and in old people. Scurvy in the infant was first accurately described in 1883 by the English physician Barlow, who clearly demonstrated its close similarity to the disease in the adult. The classical symptoms of acute scurvy in children are only too well known. The child, generally a poorly nourished infant, lies quietly in bed in a somewhat characteristic position, usually with one thigh everted and flexed on the abdomen. If the legs are touched the child shrieks with pain, and on examination one or both thighs are found to be swollen and tender. If the teeth are present, the gums in relation to them are red and swollen and bleed at the least touch. It must be remembered, however, that these acute symptoms are only manifested when there is a complete lack of vitamin C in the diet. With sub-minimal amounts in the food, latent scurvy results, a condition closely akin to the chronic form of scurvy produced experimentally in the guinea-pig. In the child with latent scurvy there are no definite symptoms except listlessness and failure to put on weight. As Hess has pointed out, the condition of latent scurvy is probably the commonest type of the disorder, especially in the larger cities where almost the entire milk supply for infants is pasteurized.

In adults, acute scurvy differs in certain particulars from the form seen in children. The earliest sign is usually a change in the complexion, the color becoming characteristically muddy. Frequently too, swelling of the pinna of the ear is found in the initial stages, especially if the patient has slept on a hard pillow. There is often also an enlargement and thickening of the hair follicles of the inner and anterior aspect of the thigh and upper part of the leg. In the later stages the gums become soft and swollen and bleed very easily, while firm tender swellings may appear in the muscles and deeper tissues, more especially in the calf mus-

cles of the leg. These brawny swellings are due to hemorrhage into the tissues. As in the case of the child, so too with the adult, the disease is more often present, not in an acute, but in a latent or subacute form, uncharacterized by definite clinical symptoms.

In the acute form of scurvy the main pathological changes are to be found in the blood vessels, more especially in the lining cells of the capillaries. Degenerative changes occur in these cells with the result that the delicate capillary walls are easily ruptured. Changes associated with fibrosis of the pulp, are also met with in the teeth.

In chronic scurvy there are no very definite lesions in the vessel walls, with the result that hemorrhages are much rarer; nevertheless, certain important pathological changes do occur more especially in the blood-forming bone marrow.

Bodily Defenses Weakened

It is well known that one of the main ways in which the body wards off the attacks of pathogenic micro-organisms is by means of certain of the white cells in the blood—the polymorphonuclear leukocytes. These polymorphonuclear leukocytes, which have the power of ingesting and destroying bacteria, are found in the bone marrow. The invasion of the body by bacteria is the signal for an increased formation of polymorphonuclear leukocytes by the marrow. If for any reason the blood-forming marrow is damaged the number of leukocytes poured out into the blood stream is insufficient and as a result the bacteria flourish unchecked. Now, in the chronic form of scurvy, there are found experimentally very definite degenerative changes in the bone marrow. The blood-forming cells are replaced by masses of fibrous tissue or by gelatinous-looking material. If, now, an animal suffering from this chronic form of scurvy be inoculated with pathogenic bacteria, such as *Pneumococcus*, *Streptococcus*, or *Bacillus coli*, the leukocytic response is insufficient, the bacteria grow unchecked and the animal succumbs to a much smaller infecting dose of the organism than a control animal fed on a diet containing ample supplies of vitamin C.

The antiscorbutic vitamin has thus a double rôle to play in nutrition, for not only does it prevent scurvy, but its presence in sufficient amount in the diet is essential if the tissues are to resist successfully the attack of common pathogenic micro-organisms.

Fresh Air Outings in Child Care— The Medical Point of View*

*One May Properly Suggest the Importance of Careful Inquiry Into the
Purposes, Administration, and End Results of
Fresh Air Outings*

BY IRA S. WILE, M.D., NEW YORK CITY.

IN DISCUSSING fresh air outings as a factor in child care, it is necessary to differentiate outings for the purpose of prevention or the cure of disease, outings as recreation, and outings to tide over social situations. Obviously, from the standpoint of recreation, or the meeting of temporary familiar problems, the time element is partially determined by the nature of the home situation, or by the number of children to whom recreation is to be given, in terms of the relative amount of recreational opportunity available.

There appears to be a somewhat natural seasonal variation in the fresh air outings, which is not dependent upon medical situations. The need for convalescent care exists throughout the year, as does a considerable amount of relief for the control of social factors. The demands of school and the handicaps of rigorous climatic conditions appear to throw the peak load of fresh air outings upon the summer months. It is during the summer period, particularly, that the medical question arises as to the period of stay at a fresh air home. There is a definite question as to the value of the day's outing, insofar as it applies to specific medical conditions. Casting aside the tremendous strains upon mothers, incident to giving a family of children a day's outing, one may ask the degree to which bodily health is advanced by day boat trips or train trips to nearby places. Undoubtedly an occasional

measure of gain is secured through the exposure to the sun's rays, the freedom for play and exercise, and the increased pleasure that comes from holiday food supplies. There is not

equaled in terms of physical improvement for the majority of children to whom such advantages are offered. Considering the tremendous number of children who actually require open

air treatment, it is most likely that outings of this character fail to produce communally vital results warranting their continuation. The floating hospital is not to be considered as a fresh air outing, but as a particular form of hospital, designed to meet the needs of children with acute illnesses, or to supply a means of improving the opportunities for rapid convalescence. Certainly so far as tuberculosis, rheumatism, heart disease and convalescent states from various diseases are concerned, the day's outing is valueless.

A tendency too frequently noted among institutions is the desire to represent in their annual reports that they have given fresh air care to large numbers of children. These total figures are sometimes exceedingly high, but they are by no means indicative of the medical service provided, or the physical advantages yielded to the children thus cared for. No one will

deny that two weeks in the country is an excellent prescription for any city child, and that the results of it may redound to the physical improvement of children. On the other hand, two weeks' outing care for a child with heart disease, chorea, rheumatism, evidences of malnutrition and anemia, or other constitutional weaknesses, by no means represents adequate treatment. Outings in these cases should be prolonged and should include complete medical care.

It would appear to be desirable to

Fresh Air for Selected Groups

SINCE it is not possible to furnish fresh air recreation for all children for whom it is considered socially desirable, what system of selection is to govern the distribution of such privileges? The author believes that the fresh air facilities offer the best solution of the crying need for convalescent care, and that first choice of fresh air and recreational agencies should be given to patients discharged from hospitals, or persons who are dispensary charges, or who are under the supervising care of private physicians. At least fresh air camps should be evaluated and placed accordingly in their proper place in a general scheme of preventive measures. The preventive values of fresh air would then appreciate in meeting the problems of all subnormals, mental and moral, as well as in rehabilitating the purely physical sub-standard children.

merely a raising of the morale of children, but, incidentally, a small measure of stimulation, which is advantageous. The actual effect upon health is negligible.

Boat outings, continued over a period of days, provide a larger measure of benefit, by reason of the extra nursing care, the supervised dietary, and the relief from the dust, the crowding, and oppression of the congested homes of cities. It is dubitable in my mind whether the actual per capita cost of outings of this type is

*Read at the "Get Together Fresh Air Conference" called by the Committee on Fresh Air and Convalescent Care of the Children's Welfare Federation, New York City, May 8, 1923.

adjust the plans for outings throughout the year, in such a manner that the period of stay would be determined by the needs of the individual child. Many institutions would care for a smaller number of children, but their actual number of days' care would be identical, and the medical results of their service would be of greater communal benefit. When one realizes the degree of time and care given in preventoriums, camps, and roof health resorts to build up the physical well-being of children, so as to protect them against tuberculous infection, one may appreciate how far the time element is concerned in the actual preventive methods. Similarly, when one recognizes the number of days involved in restoring to functional activity children with cardiac disease, one realizes to what extent short periods of time fail to achieve desirable ends.

The short period away from home may be fraught with danger, unless there is full opportunity for medical oversight, following upon a preliminary medical examination, in view of the necessity for a rational control of dietary and exercise, as a means of promoting physical welfare.

The primary purpose of fresh air outings and convalescent care should be to restore to their maximum functional activity, the half cured individuals, who are discharged from hospitals. While one speaks of fresh air in all these forms of care it must be recognized that while sunlight and oxygen are of paramount value, they are not more important than the provision of proper food, the supervision of exercise, the relief from the noise, turmoils, strife, and unhappiness of homes, and the amusement, diversion, recreation, and occupation, which constitute elements in rational convalescent care. From the medical standpoint fresh air outing should be provided, together with convalescent care, for children who have undergone surgical treatment, those who are handicapped by carditis, rheumatism, arthritis, bone and joint tuberculosis, children with temporary mental disorders, and a large variety of nervous diseases and, indeed, adolescent children undergoing physical and mental difficulties and maladjustments. The problem of after care is bound up in convalescent care and outings.

Brown, in 1911, estimated that 60 per cent of the surgical cases and 40 per cent of the medical cases in hospitals for acute diseases require organized convalescent care. Of this

number he estimated that 20 to thirty per cent would be eligible for a convalescent home. These figures deal, of course, with all types of hospital patients. If one were to consider the figures for children, the percentage would probably be about the same, except that a larger percentage might be eligible for the convalescent home. It has been amply demonstrated that the city, itself, with adequate home supervision, guidance, and direction, does not offer insuperable difficulty to the maintenance of reasonable health.

Considering the population, it is not possible to make provision for all the children to whom, from a social standpoint, it would be desirable to offer the fresh air recreational facilities. Therefore, it becomes more impera-

would recognize more fully its responsibility for extending its ideas of health administration to cover convalescence. Thus the sick, handicapped or sub-normal child under hospital auspices, might receive the follow-up care essential to promote its highest functional efficiency.

Of Social Value

I recognize that a large number of children do not come into intimate contact with medical service as early as might be desired, and that their needs are first ascertained through philanthropic agencies, social settlements, and similar organizations interested in promoting the well being of families. Medical examination of evidence of incipient or advanced organic disease or may reveal definite constitutional or functional weaknesses, incident to living in a home with an inadequate income, or in surroundings fraught with physical or mental hazards. Every fresh air agency should require a physical examination and reasonable diagnostic explanation for the admission of children to its groups, and at least an assurance of freedom from contagious disease.

From the social standpoint there is no doubt that an outing of varied duration would be of inestimable value, although the end result of short stays would be quickly overcome by a return to the home with its impoverishment, ignorance, indifference, neglect, or familiar strife. The question may be properly raised as to whether the value of fresh air care is of permanent worth. It would appear to me essential to evaluate fresh air work in terms of their definite objectives. Is the purpose to give children a good time, a temporary respite from the trials and tribulations of childhood, the oppressiveness of city life and home surroundings? Is the aim to provide temporary shelter in social emergency or to transfer the burden of temporary relief from one type of philanthropic agency to another social group? Is it purposed to afford a temporary building up of physical health, in order to give greater strength to meet the hazards of a return to urban life? Is it designed to effect the permanent cure of some particular malady or restore to functional power in such a manner as to lessen the likelihood of the return of the specific physical or mental handicap? Is it to be purely convalescent care or physical care plus oversight, hyperalimentation, supervised exercise, occu—(Continued on page 658)

"I don't drink tea or coffee. I like bread and butter." The New York Tuberculosis Association trains children in habits of health.

tive to make adjustments in such a manner as to yield the fullest measure of benefit to those most requiring communal care of the type being discussed. This involves some definite system of selection. I believe that the first element in the population to be considered are those who are to be discharged from hospitals, or who are under care in various dispensaries or by private physicians.

Dr. Frederick L. Brush has referred to convalescent work as "serving as an extension arm to the hospital," and this would appear to be a type of development meriting considerable thought. By so doing, the hospital

Facilities of Warren County Bacteriological Laboratory

The Physicians of This County Have Worked Out An Adequate Service for Hospital and Community, Serving Part of Three Counties

By MORRIS MASLON, M.D., DIRECTOR, GLENS FALLS, N. Y.

DURING the year 1910 the New York State Department of Health, carrying out its policy, at that time, of trying to establish laboratories in the various counties in the state, was able to convince the physicians of Warren County of the necessity of having a laboratory located in their county, and of the benefits which they would derive from having facilities for laboratory service near at hand.

These physicians, appearing before the Warren County Board of Supervisors at one of the regular meetings of the board, were so successful in convincing them of the importance of having a diagnostic laboratory in their vicinity and of the immense benefits which the residents of the county individually, and the county as a whole would derive from having this laboratory in their midst, that the following resolution was immediately adopted by them:

Resolved: That the Board of Supervisors of Warren County, pursuant to Section 43 and 44 of the County Law, establish a county laboratory to be known by the name of the Warren County Bacteriological Laboratory. That this laboratory shall be maintained at the Glens Falls Hospital according to an offer made by the board of directors of the hospital, viz.: That the hospital shall furnish light, heat, and water for the same with the understanding that the services of the attending bacteriologist shall be free for all patients in the hospital.

That said laboratory shall be governed by a committee of three members of the board and two practicing physicians of the county. That the governing committee shall select and recommend for appointment to the board of supervisors a competent bacteriologist who shall devote his entire time to the work of the laboratory.

That examinations relative to all communicable diseases shall be made free of charge for all people of Warren County, and also all examinations in which the community at large is the beneficiary, but in those cases in

which the individual is the beneficiary, a charge shall be made.

All moneys received from the fees shall be paid to the County Treasurer on the first day of each month.

The Warren County Bacteriological Laboratory, as it is now called, was, therefore, officially established at the Glens Falls Hospital in Glens Falls, and at once served a dual purpose:

tion, and all autopsy work for the coroners. In addition, the laboratory acts as a substation for the state laboratory, and keeps on hand at all times in a properly cooled place, and easily accessible to the physicians, a full supply of various antitoxins, vaccines, and all laboratory supplies necessary for the health officers. A small

charge, graded according to the work required is made for all examinations where the individual alone is benefited by it. This work is performed for the physicians of the county and, in order to bring the facilities of the laboratory within the reach of all the people of the county, the fees were purposely made rather nominal. The fees collected by the laboratory, and turned over to the county treasurer, serve to pay the running expenses of the laboratory. The scope

of this work is as follows: Complete blood examinations, stomach analyses, stool examinations, complete urinalysis, all bacteriological examinations, cultures and smears, renal function tests, blood chemistry and tissue examinations.

The laboratory was originally housed in one room furnished by the hospital, in the hospital, and was equipped at an initial cost of about a thousand dollars. The personnel consisted of one worker—the writer—a physician who devoted his entire time to the work of the laboratory. The equipment, of course, in the beginning, owing mainly to lack of space and but partly to lack of funds, was moderate, though fairly complete. However, the work of the laboratory increased to such an extent, that additional apparatus and housing room soon became a necessity; also, the work required by the community and hospital increased to such an extent that additional workers in the laboratory were needed. An agreement was recently entered into with the directors of the Glens Falls Hospital

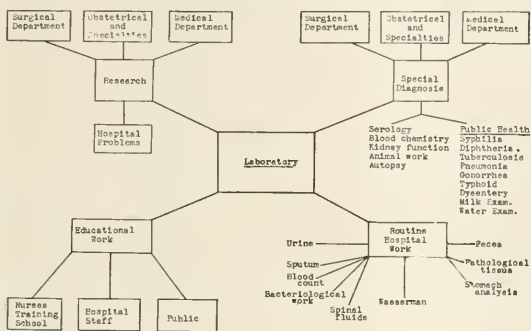

Fig. 1.—Chart showing internal relationships of the services embodied in the laboratory and points of contact with larger professional and community interests.

Acting as a public health laboratory, it furnished laboratory services to the county as a whole and diagnostic facilities to a population of thirty-two thousand, it served, too, as a general hospital having a capacity of about seventy beds. Also, the geographical location of Glens Falls, just on the border line of two other counties, and close to three fair size communities, the diagnostic facilities of the laboratory serve parts of two neighboring counties.

In accordance with the original resolution passed by the Board of Supervisors, all public health work for the county—which means all work required by the various health officers of the county—is done free of charge. The scope of this work includes water and milk examinations, the diagnosis of enteric diseases, sputum examinations for tuberculosis, sputum typing for pneumonia, the examinations of smears for gonococci, the dark field examination for syphilis, the examination of spinal fluids for meningitis, throat cultures for diphtheria, collection of blood for Wassermann reac-

whereby they would furnish additional room for the laboratory and charge a nominal fee to all private patients entering the institution for treatment or diagnosis, which fee would permit all patients in the hospital, whether public or private to receive unlimited laboratory service. A fund was created to enable the laboratory to provide additional equipment, and pay the salary of at least one and possibly two technicians. Furthermore, owing to the kindness of a lady resident of Glens Falls, who wishes to remain unknown and to whom we take this opportunity of publicity acknowledging our thanks the sum of one thousand dollars was donated for additional laboratory equipment.

At the present time the Warren County Laboratory is housed in two rooms, well furnished, with a personnel consisting of a director and one technician, and with equipment which we believe is probably the best of the smaller laboratories, and perhaps the equal of some of the larger laboratories in New York. The present indications are that the laboratory already needs not only additional room, but more technical assistants.

The function and scope of work of the Warren County Laboratory can best be illustrated by the accompanying diagram, (Fig. 1), and by a resumé of the work done for the six months from December 1, 1922 to June 1, 1923. A detailed statement of the equipment exclusive of chemicals etc., follows:

Laboratory Equipment

- A. Pathological and Bacteriological Department.
- 1 binocular microscope with mechanical stage.
 - 1 monocular microscope with mechanical stage.
 - 1 hand microtome for collodian sections complete with two knives.
 - 1 freezing microtome complete with gas tank and two knives (automatic).
 - 1 steel cabinet for filing pathological slides.
 - 12 museum jars for pathological material, assorted sizes.
 - 2 microscope lamps, electric.
 - 1 dark field illuminator.
 - Staining dishes, section lifters and needles for pathological sections.
 - American slender dishes with ground covers for slides—12.
 - 1 autopsy set complete (instruments) in canvas cover.
 - 1 Frens electric incubator, 18x16x20 on stand.
 - 1 Frens electric oven, 12x12x12.
 - 1 Arnold sterilizer.
 - 1 autoclave, gas heated, vertical form.

- 1 sterilizer, hot air, Lautenschlaeger Form.
- 1 sterilizer, hot air, Lautenschlaeger Form, high.
- 1 water still, automatic.
- 1 large centrifuge, International electric. S tube head, with Babcock trunnion cups, complete.
- 1 large water bath for serological work.
- 1 small water bath.
- 1 bacteria counting apparatus, Wolfhuegels, complete.
- Petri dishes, standard size..... 100
- Platinum needles..... 4
- 1 c.c. pipettes graduated 1/100..... 100
- 5 c.c. pipettes graduated 1/10ths..... 20
- 10 c.c. pipettes graduated 1/10ths..... 15
- 100 c.c. pipette..... 1
- 50 c.c. pipette..... 1
- Bunsen burners..... 6
- Flasks, boiling, Pyrex, 2000 c.c..... 2
- Flasks, boiling, Pyrex, 1000 c.c..... 7
- Flasks, boiling, Pyrex, 500 c.c..... 4
- Erlenmeyer Flasks, 1000 c.c..... 3
- Flasks, boiling, Pyrex, 250 c.c..... 2
- Erlenmeyer Flasks, 500 c.c..... 3
- Erlenmeyer Flasks, 250 c.c..... 3
- Erlenmeyer Flasks, 100 c.c..... 9
- Erlenmeyer Flasks, 50 c.c..... 6
- Test tubes, assorted sizes..... 750

Fig. 2.—Rear view of the main room of the Warren County Bacteriological Laboratory.

- Staining bottles (dropping)..... 12
- Staining jars, Coplin..... 12
- Dyes (powder form), culture media material, Slides (glass) test tube racks.
- Wire baskets..... 20
- Pipette containers, copper..... 4
- 1 Van Slyke and Cullen urea apparatus for 8 determinations.
- B. Blood Chemistry and Estimation of Renal Function.
- 1 Dubosq colorimeter.
- 1 Bock-Benedict colorimeter.
- 1 Van Slyke Co. apparatus, complete.
- 1 Van Slyke and Cullen urea apparatus for 8 determinations.
- 1 suction and blow motor.
- 1 analytical balance sensitive 1/10th milligram.
- 1 coarse analytical balance.
- 2 burettes, Schellbach with three way glass stopcock.
- 2 burettes, Morse calibrating three way glass stopcock.
- 12 Myers sugar tubes, graduated 3, 4, 10, 15, and 20 c.c.
- 12 sugar tubes graduated 12.5 and 25 c.c.
- Volumetric flasks:
- One..... 2000 c.c.
- Three..... 1000 c.c.
- Two..... 500 c.c.
- One..... 250 c.c.
- Two..... 200 c.c.
- Three..... 100 c.c.

- One..... 10 c.c.

C. Clinical Pathology:

- Blood coagulation time apparatus..... 1
- American standard Haemacytometers with Levy counting chambers double complete..... 2
- Counting chamber with Fuch-Rosenthal ruling..... 1
- Haemocytometer, Sahli..... 1
- Blood lancet, spring, automatic..... 2
- One funnel support, 6 funnels..... 1
- Dessicator with plate..... 1
- Burette stands with clamps..... 6
- Burettes, straight, capacity 100 c.c..... 2
- capacity 50 c.c..... 2
- Reagent bottles with glass stoppers..... 13
- Beakers pyrex glass assorted sizes..... 16
- Burette automatic Squibbs..... 2
- Ureometers, Squibbs..... 2
- Albuminometers, Esbach..... 6
- Milk test bottles, 8%..... 24
- Cream test bottles, 50%..... 4
- Cylinders with rim top high..... 4
- Crucibles..... 6
- Ureometer..... 2
- Glass mortars—with pestle..... 2
- Milk dilution bottles..... 43
- Water sample bottles, glass stoppers..... 5
- D. Miscellaneous:
- 1 desk.
- 1 typewriter with desk complete.
- 1 electric fan.
- 1 steel filing cabinet for papers, records, etc.
- 4 large, loose leaf, record filing books.

Resumé of Work

The total number of specimens examined from December 1, 1922, to June 1, 1923 was 3,655. Supplementary tests amounted to 1,794, making 5,449 tests in all. Some of the more important, from a numerical point of view are as follows:

	Number of Specimens
Diphtheria (diagnosis).....	127
Diphtheria (release).....	505
Diphtheria (carrier).....	32
Typhoid and paratyphoid.....	58
Gonorrhea.....	87
Tuberculosis.....	96
Urine analyses.....	1,775
Cell counts and hemoglobin complete.....	155
Differential counts only.....	101
Chemical analyses of blood.....	298
Pathological specimens.....	191
Milk examinations.....	102

Diphtheria Susceptibility Less Among the Poor

Based upon the results of a study of the Schick tests and immunization against diphtheria conducted in the eighth sanitary district of the state of Vermont, Dr. C. W. Kidder, field agent of the United States Public Health Service, states that both the percentage of persons susceptible to diphtheria and the degree of their susceptibility are higher among rural than urban populations, and that both are higher than that of the well-to-do in cities, than in the rural as well as in urban communities susceptibility and incidence are higher among the well-to-do than among the poorer classed, and that native born persons are much more susceptible than the foreign born.

Stockton's Municipal Camp at Silver Lake

Here Campers Experience the Joy of Cold Water, Strong Winds, Long Roads, Brown Earth, Open Fires, Climbing, Swimming, and Strenuous Outdoor Sports

BY STELLA S. SWENSON, CAMP DIRECTOR AND MANAGER, STOCKTON, CALIF.

A NOTEWORTHY thing has been happening the past few years in Stockton and all over our country. Business men and women are discovering a new, continuing element in life—or rather a new application of an old element, the element of play or a good time. The members of the Stockton, Calif., Playground and Recreation Commission have been proclaiming persistently the importance and necessity in life of recreation and play for the adult as well as the child and have been steadily and gradually creating more opportunities for the leisure time of the citizens.

On July 29, 1922, Stockton's Recreation Camp at Silver Lake, on the scenic Alpine Highway, one hundred miles from Stockton, was dedicated to the future health and happiness of the people. It is located, through the kind co-operation of the United States Forest Service, in the El Dorado National Forest, near the route blazed across the Sierra by Kit Carson, the famous scout, when he piloted John C. Fremont across the mountains to California in 1844. Although this road crosses the Sierra at a higher altitude than many of the other routes, the climb is more gradual. For nearly thirty miles the road keeps close to the top of a ridge leading up to the top of the high Sierra. Were it not for the change in the character of the trees—bull pines give way to the mountain pines, and these in turn to the yellow, white, and sugar pines, to firs and cedars and finally to the gnarled and rugged junipers, which are found in the Sierra only at high altitudes—the ascent would hardly be

appreciated. The glacial lakes, three miles long, at an elevation of 7,240 feet, are surrounded by meadows and numerous high bluffs and peaks of unusual historic, geographic, geological, and botanic interest with California's Alpine woods of fir, tamarack, hemlock quaking aspens, and storm beaten junipers circling and towering above all. It is in such a locality as this

but a necessary part of life. The experience of the first season's activities indicate that the attainment of this end is well under way. The total attendance from July 15, to October 1 was 374. Of this number 208 were citizens. Six of these were in camp for a period of three weeks, 44 for two weeks, 42 for one week, and 116 spent week ends at Silver Lake.

From July 15 to July 30, Miss Edith Tubbs, executive secretary, the loved leader of the Camp Fire Girls, affectionately called "Chepalo," directed the activities of the camp for the Camp Fire Girls. She was ably assisted by some twenty-five counsellors who were mature women and who had the health and safety of the girls in mind. The major activities were each directed by some one counsellor who was a specialist in that particular field. The girls followed a very happy daily program, cardinal principles of work, health, and love.

Group of Camp Fire girls making pine needle baskets, trays, and vases at the Stockton Municipal Camp.

that Stockton has a thirty-one acre camp site. A large number of men and women contributed of their time, money, thought and automobiles to put this mountain recreation project under way.

It is the aim of the supporters of this project to provide at the lowest possible cost to the citizens and taxpayers of Stockton an outing in the health-giving, pine- tonic atmosphere of the high Sierra. The directors aim to provide a camp life where Stocktonians may enjoy the sturdy, simple life of the great out-of-doors and may seek the beauties of nature, friends of health, and happiness. It is hoped to demonstrate in a definite concrete manner that camping is not a luxury

To obtain the most from camp and in order to develop a well-balanced life, many girls worked hard for the Minkalo Rank and the Wohelo Legion. The results of their achievements, the honors and ranks, were bestowed at a beautiful ceremony called the Grand Council Fire. The climax of the joyous life and beautiful sentiment and spirit of the girls' two weeks at camp was expressed in the original pageant "Silver Lake, The Camp of Dreams." One hundred and fifty-six girls and counsellors participated in the pageant. It portrayed the primeval forest, careless campers, nature laws and the growing spirit of co-operation and appreciation of the great outdoors; the

Getting ready for the daily swim. Great precautions are always taken. Water sports are directed by life saving guards and instructors in swimming, boating and canoeing.

government's forest policy and the giving back to the people of portions of the public domain for national parks and public camps, special stress being laid on the municipal camp idea which is growing in the west.

Following the two weeks during which the activities of the municipal camp were largely devoted to the encampment of the Camp Fire Girls the camp was used by men, women, and children from the city of Stockton. For the more ambitious campers were available the "joy of cold water, strong winds, long roads, brown earth, open fire, friends on the hike, swimming, diving, rowing, the road to the hill and around the lake." For those who desired the less strenuous activities camp was the place for rest, sound sleep, regular habits and the joy of living.

Some of the activities that may be enjoyed at Silver Lake are: boating, fishing, hiking, and mountain climbing, canoeing, horseback riding, nature lore, swimming, mountain craft, games, singing, dancing, evening entertainments of song, stunts, and story around the camp fire. For those who delight in hiking, exploring, climbing higher and higher for majestic scenery and nature's hidden treasure there is an opportunity for longer and shorter hikes, and also overnight sleeping bag trips to points of unusual interest.

A war canoe holding twelve to twenty persons may be rented at a nominal sum. Nothing is better in training

for team work or unity of action and nothing is prettier than the even rhythmic sweep of a dozen or more paddles.

Mineral Bay, a secluded cove on Silver Lake offers a good sand beach for swimming.

This camp does not accept applications from people in poor health. It is purely a recreational

project for the citizens and tax payers of Stockton. The rates are:

	Adults	6-10 yrs.	3-5 yrs.	1-3 yrs.
Two weeks...	\$25.00	\$20.00	\$15.00
One week...	17.50	15.00	12.50

Children are wanted and welcomed at

The interior of the temporary kitchen. Two paid cooks and two paid dishwashers and handy men are employed. The campers give one hour of camp service each day; usually consisting of preparing the fruits and vegetables, setting the table and serving meals, and planning the Camp Fire program. Over week-ends 260 have been served at one meal.

the camp and special activities are conducted for them two hours every day.

Owing to the low cost, each camper is required to render an average of one hour's service daily as outlined by the camp director. No fire arms are allowed in the camp, boats, horses and guides are for hire, and the Stockton Public Library maintains a branch at the camp during the summer.

The equipment consists of a rustic log cabin, 32x64 feet, for a social hall and dining room with fireplace, piano,

violin, the small library just mentioned, tables and chairs; 24 floored tents each in a picturesque setting; 135 individual cots, with mattresses and mattress covers. Campers are required to furnish their own blankets. An excellent athletic field provides space for all kinds of games, and a children's playground with apparatus and play equipment is a special attraction. Cool and safe water is piped from mountain springs and all sanitary facilities of the camp are in accordance with specifications of the United States Forest Service. An outdoor fireplace, crowned with a pine tree theatre affords an artistic setting for twilight and evening gatherings.

The Log Cabin Lodge, the first permanent unit of the camp, is built of tamarack fir, and granite. It has been characterized by the National Forest Supervisor, as the finest log building in the mountains. This was in process of construction last summer but is in use this season.

Last year a genuine piece of service was contributed by one of Stockton's kind and generous women when fifteen women and children were given the opportunity to enjoy the camp and become healthier.

This brief description and collection of facts shows what can be done by a municipality to furnish its citizens with excellent recreation at a nominal cost.

The indications for the 1923 season promise even greater success will attend this year's activities than was experienced in 1922.

The Log Cabin Lodge at Silver Lake, the first permanent unit in the camp. It was built by the city of Stockton through its Playground and Recreation Department.

Complexity of the Sewage Disposal Problem of Chicago

Normal Capacity of Present Drainage System Has Been Reached. Its Further Expansion Presents Great Engineering Difficulties and Enormous Expense

BY HARRISON P. EDDY, METCALF & EDDY, CONSULTING ENGINEERS, BOSTON, MASS.

THE sewage of Chicago originally was discharged into Lake Michigan, either directly or indirectly, chiefly the latter, by way of Chicago River. At the same time the water supply of the city was derived from intakes not far remote from the shore. Thus opportunity was continuously afforded for the mingling of the sewage with the waters drawn for domestic supply. This was a condition not only abhorrent to the sentiments of the people, but one fraught with grave danger because of the possibility, if not the certainty, of the transmission by these means of typhoid fever and other water-borne diseases.

A remedy for this condition was sought, and in 1899, only about thirty-four years ago, the Sanitary District of Chicago was formed, with a population of approximately one million persons, and a tributary area of some 185 square miles. Since then this area has been increased from time to time, until in 1921 it comprised nearly four hundred square miles.

The object of the formation of the Sanitary District was "to safeguard the health of the city by so disposing of the sewage that it shall not contaminate the waters of Lake Michigan, the source of water supply."

The major works built by the Sanitary District are illustrated by Figure 1, which also shows a number of the waterworks intakes and their position with reference to the mouth of Chicago River and to the shore line.

This great project may be divided into several sections, the most important being the Main Channel built from Robey Street in the city, to Lockport, a distance of twenty-eight miles. Here it discharges into the Des Plaines River the channel of which was improved for a distance of about six miles to Joliet below which

the Des Plaines River joins with the Kankakee to form the Illinois. The South Branch was improved from the Lake to the easterly end of the main channel at Robey Street. This main channel with the river improvements at either end permitted the reversal of flow in Chicago River, thus sending the sewage which previously flowed to the lake, in a westerly direction to Des Plaines River, and thence through Illinois River to Mississippi River at a point just above St. Louis.

In order that the Des Plaines River, which is parallel with and close to the Drainage Channel, might not overflow its banks when in flood and pass into the Drainage Channel, the river channel was improved for a distance of about thirteen miles above Lockport and nineteen miles of levees were constructed.

It was not intended that these channels, which permitted the reversal of the flow of Chicago River, thus preventing the sewage from reaching the lake, should be open sewers, but provision was made in the charter for the drawing of water from the Lake to the extent of $3\frac{1}{2}$ cubic feet per second for every 1,000 persons. This is equivalent, approximately, to 2,150 gallons per capita per day, which, with the quantity of sewage flow of about three hundred gallons per capita per day results in an allowance of 2,450 gallons of water a day to each person. This amount is available for carrying away the waste products of the community.

Dilution of Sewage

The difficulty in treating sewage so that it shall not be objectionable is due in large measure to the very small, one might say minute, quantity of impurities present in it. It is like the proverbial needle in the hay mow. Only one-tenth of one per cent of the weight of the sewage comprises its impurities. In fact, that is a relatively large estimate. It amounts to only eight and one-third pounds in a

thousand gallons, or four-tenths of a pound in a barrel of fifty gallons. Of these impurities only one-half constitute the objectionable substances, so that after all, treatment of the sewage is required to take out, or change the character of only about two-tenths of a pound of organic impurities in a barrel of sewage.

The sewage of Chicago has been disposed of thus far primarily by the process known as dilution. This is afforded by the water to which I have alluded as being drawn from the Lake. As long as the proportion of sewage to the given volume of water is not too great the quantity of impurities in the sewage, spread out through a large volume of water, are carried away from the city without the production of objectionable conditions.

In 1889 the population of the city was about one million, as previously stated. In 1920 that population had risen to nearly three millions. The quantity of water provided by the charter, to be drawn from the lake in 1920, therefore, would be about ten thousand cubic feet per second. This quantity, I think, is materially in excess of the quantity which the Federal Government has formally permitted Chicago to draw.

The quantity of polluting matter contributed by the population now tributary and the large industries which discharge polluted liquid wastes, has today become so great that the normal diluting capacity of this drainage system appears to have been reached. It is, therefore, of the utmost importance that the district should plan, as it is now doing, measures necessary for so treating the sewage before it reaches the drainage channels that it shall not create objectionable conditions.

Other Processes Available

There are a number of processes available for such treatment, the practicability of which depends upon

*Reprinted through courtesy of the Journal of the Western Engineering Society, Chicago, Illinois.

the extent of purification required and their local feasibility. The organic matter in the sewage, as I have stated, amounts to only about two-tenths of a pound in a barrel of sewage. This matter may be classified as follows: There are the large, coarse, floating solids; there are the heavy mineral matters such as sand, bits of crushed stone and cinders; there are the finer of the coarse suspended solids, which are relatively small and yet are easily seen by the naked eye, and finally there are the dissolved substances and also the colloidal matter which may be grouped with them.

But it is the bacteria in the sewage which are of primary importance with respect to the public health. Many of these are harmless—in fact, are beneficial in their life work—while others may be, and undoubtedly are, pathogenic and, under certain conditions, would be distinctly harmful.

The processes of sewage treatment have to do with the removal or the transmutation of these several classes of materials. It may sometimes be desirable to remove from the sewage the coarse mineral matter, in order to prevent its doing injury to the pumping machinery or unfavorably affecting the performance or other features of the treatment plant. This may be accomplished by the installation of a grit chamber, which is nothing more nor less than an enlargement of the sewer, providing retardation of flow and an opportunity for the settling out of the heavier detritus. The efficiency of such a chamber depends in large measure upon the rate of flow through it, and its length must be such that the particles which it is desired to remove will have settled, before they reach the outlet, to a depth which will prevent their passage. Owing to the variation in the flow of sewage a uniform velocity is

difficult to maintain and, unfortunately, unless the flow is maintained at such a speed as to admit of only the deposition of the silt, sand, and gravel, such organic matters as fruit seeds, coffee grounds, and bits of offal will settle out and result in offensive conditions. Experiments made at Rochester indicate that for conditions in this country a mean velocity of approximately one foot per second is satisfactory.

If it be simply necessary to take

permissible loss of head. It is usually set at right angles to the axis of the channel, but if this be very narrow additional rack area may be gained by constructing it curved in plan or by setting it on a very flat slope. Experience at Boston has indicated that the desirable area of rack is not less than 150 per cent of that of the channel leading to it.

Sometimes a series of racks is used, as for instance at Manchester, England, where the first is composed of

1x4½ inch bars set six inches apart, and is destined to catch large timbers and heavy matter which would break a lighter structure. From this the sewage passes through a rack of ¾ inch bars set 1½ inch apart, and thence through a grit chamber, from which it goes to the third and final rack, of ¾ inch bars with ½ inch openings.

Where the racks are "fixed," or set stationary, it is necessary either to rake them by hand or to utilize some mechanical combination of rakes and brushes. Hand cleaning involves a great deal of labor, especially where the racks are set at a considerable depth below the operating floor. Movable racks have, therefore, been evolved, of which there are a number of types, the most popular in this country being the so-called "cage screen." This consists of a plate or grid bottom and three sides of bars or rods spaced about an inch apart. The fourth, or open, side is placed broadway of the channel and receives the flow, the sewage pass-

ing out through the back and to some extent also through the sides. When it is necessary to clean the cage it is raised to the surface, carrying in it the accumulated debris and trash. Usually a duplicate screen is provided which can be immediately lowered to take its place. This type of rack also is sometimes used in series, as at the Ward Street Station in Boston. Here also the first row of ¾ inch bars has

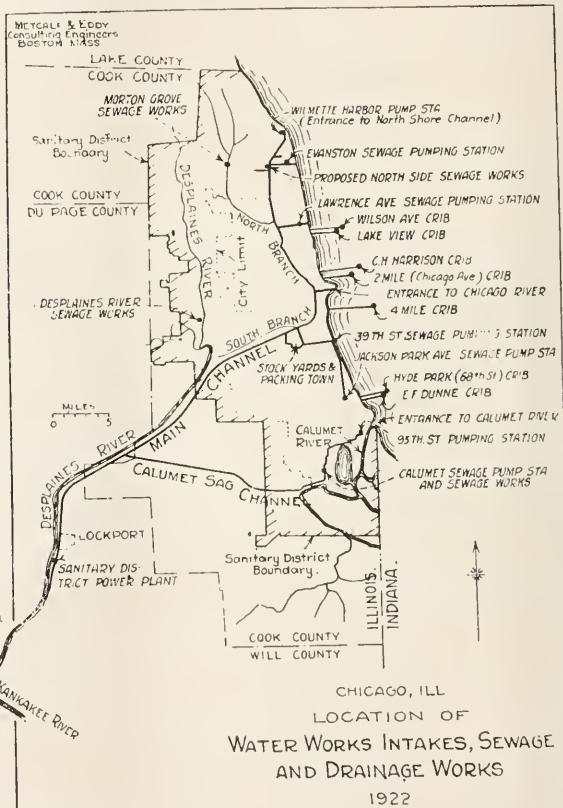

Fig. 1.—Map of Sanitary District, showing relation of water supply and sewage disposal works.

out the very coarse substances, this may be done by the use of racks. These are constructed of either square or round bars about ¾ inch in size, set parallel and spaced from ½ to 1½ inches in the clear, depending upon the character or the amount of the material which it is desired to remove. The length of rack depends on the amount of sewage to be screened, the size of openings, and the

been supplemented by a second row staggered behind them at such intervals as to give an actual diagonal measurement between bars, of 1 inch. The resulting ratio of screen opening to sewer area, with one screen only operating, is 162 per cent and with both screens 324 per cent.

Of the other movable racks there is the wing type, formed like a paddle wheel, the vanes consisting of bar racks which sweep downward through the sewage and up clear of it, with their load of screenings. These are mechanically pushed from the rack by a brush and delivered on to a belt conveyor. The essential advantage of this type is that all bearings are above the level of the sewage. The number of wings used governs their size and also the depth of depression in the channel of the sewer, through which they sweep.

Where the flow is not great three- or four-rack installations may serve, but in Germany five- and even six-rack screens are used. The Geiger rack is a modification of this wing type, the vanes being curved instead of straight. The two at Gleiwitz are 12.5 ft. in diameter and 5.9 ft. wide, with vanes composed of V-shaped rods 0.12 in. apart.

The Link Belt rack is a broad endless link belt, moving on sheaves, set at top and bottom. It is placed at an angle and may be swung completely above the sewage. At Hamburg where this type was adopted because of the range in the tides and the elevations of the sewers, the links are bars 14.2 inches long, held in angle iron frames about 9.8 ft. long and 15 inches wide. Each rack has 46 of these frames and a total of 14,000 links. It is cleaned very thoroughly by a rake with rubber tires, which extends entirely across the width of the rack.

It has been estimated that coarse screens will remove from less than 5 to perhaps 10 p.p.m. of coarse material from the sewage, whereas from 20 to 70 parts of suspended matter may be removed by the use of fine screens, under favorable conditions. Of these there are several forms. One type is the drum screen, shown in Figure 2—a revolving cylinder which permits the sewage to pass from the outside chamber into the inside

of the drum and out through the end. The centrifugal motion imparted to the sewage causes that inside the drum to rise a little higher than that in the chamber in which the drum revolves, permitting an outward flow of a small portion of the screened sewage through the meshes in the screen, thus washing off the solids which adhere to the screen. This results in the formation of a relatively thick mixture of solids in this portion of the outflowing sewage, which is carried over a baffle into a sedimentation compartment when the solids which settled out are lifted by means of a perforated bucket elevator out of the pit and dropped into a suitable receptacle. The main portion of the effluent, which passes out at the end of the drum, is conducted past the sedimentation compartment to the

chambers or fine screens, the sewage, if further treatment be desired, may be passed through sedimentation tanks. By this means not only the mineral solids but also much putrescible organic matter which would tend to form offensive sludge deposits or clog the various features of the treatment plant, may be removed. Such structures are designated either as horizontal or as vertical flow tanks depending upon the direction of flow of the sewage through them. This is governed by the shape of the tank and the place of introduction of the sewage, the "vertical-flow" tanks being usually cylindrical with the influent introduced near the bottom and overflowing at the top, while the "horizontal-flow" tanks are rectangular and shallow with the influent introduced at one end and flowing out at the other.

The tanks may be operated either upon the fill-and-draw or upon the continuous-flow method. Theoretically where the sewage is allowed to become quiescent and then after a period of settlement the supernatant liquor is all drawn off the sludge at the bottom of the tank may be disturbed and some of it may flow away with the effluent. Also with this intermittent method of operation there is a loss of available head of the sewage, which may be objectionable. Again, during the time occupied by filling and emptying, the process of purification is temporarily suspended. It has been found in practice that the volume of sludge is generally increased by its frequent removal. With the continuous method of operation, however, the sludge becomes more compact and contains a higher percentage of solids. Such tanks may be provided with baffle boards for maintaining uniformity of flow and they may be operated in series or in parallel. The sludge is drawn off through sludge pipes, some times with the aid of hand scraping or squeegeeing. This sludge may contain from 2 to 10 or even 15 per cent of solids in a given volume of sludge, and as this is removed in practically its initial condition it is frequently more or less putrescible and objectionable in character.

To overcome this difficulty with offensive—(Continued on page 662)

Fig. 2—Drum type of screen for removing coarse particles from sewage.

next feature of the treatment process.

Then there is a disc screen which, as its name implies, is a disc of perforated metal. This is set on a shaft so inclined from the vertical as to determine the tilting of the disc. The metal plates of these screens vary from 4.3 to 26.2 feet in diameter and the width of slots from 0.03 to 0.2 inches. The area of openings constitutes somewhere from 23 to 36 per cent of the whole. As the disc revolves it carries up out of the sewage the material strained away. This is removed mechanically by brushes revolving across that portion of the screen which is tilted out of the liquid. One of the most popular screens of this type is known as the "Riensch-Wurl."

After removing the coarser of the suspended matter and the heavier of the mineral matter by racks, grit

Protection Against Dust and Fumes*

Modern Industrial Concentration Emphasizes Anew the Health-Giving Amenities of Pure Air and Sunshine

BY R. C. WILLIAMS, PAST ASSISTANT SURGEON, U.S.P.H.S., WASHINGTON, D. C.

THE fact that persons in certain trades or occupations are frequently affected with special diseases or disabilities resulting from their work has been recognized for several centuries. Hippocrates, one of the earliest medical writers, in his "Epidemics" speaks of the metal digger who breathes with difficulty and is of a pale and wan complexion. Ranazzini, an Italian physician, who, about 1670, wrote "A Treatise of the Diseases of Tradesmen," was among the earliest writers who recognized and described disease resulting from the trades. Ranazzini quotes Hippocrates as stating "that when to find a sick person it behooves us to ask what measures he is under, what was the cause of it, how many days he has been ill, how his belly stands, and what food he ate," and to which Ranazzini adds "and what trade he is of."

Industrial hygiene and sanitation are usually taken to mean the hygiene of the worker and the sanitation of his working place. Modern industrial conditions have brought into being many new and everchanging problems of production, maintenance and transportation. With modern industrial development come many of the old hazards to the worker and in addition others arising from new processes and trades.

The health hazards of industry are numerous. Almost every article we use passes through at least one process that is hazardous to the worker. In the United States alone industrial accidents are estimated to cost the staggering sum of \$1,014,000,000 and this does not include other hundreds of millions that are lost from sickness due directly to health hazards of trade. The United States Government pays approximately three million dollars a year to its employees as compensation for injuries and diseases

that occur as a result of their work.

In many instances industrial accidents and sickness can be prevented. Last year the average number of days lost on account of sickness in several departments of the United States Government and several private industrial concerns was approximately eight days per employee per year. On the other hand, the National Cash

the protection of workers not only commendable as a humanitarian measure but necessary from the standpoint of economical production and the successful operation of a plant.

Place of Dust and Fumes

Dust and fume occupy an important place among the health hazards of industry. Sir Thomas Oliver designates dust and fumes as "foes to industrial life." He further states:

Dust, smoke, and fume are the product of industrial activity to be feared. In what relation do they stand to each other? Dust is usually regarded as matter in a state of fine division, but modern research shows that dust from a medical point of view is something more than this. Smoke and fume differ from dust in being the product of heat and these two again differ from each other in the respect that smoke is the outcome of incomplete combustion of hydrocarbons, such as coal, wood, and oil, while fume is, firstly, a gaseous form of metals, non-metals, and other compounds, and secondly, the return of those from the gaseous to the solid state as seen in the fleu deposit of a lead smelting factory."

Although we are more immediately concerned with the effects of dust on the lungs yet the whole body, including the skin, mucous membranes and the internal organs, suffer in due course

by exposure to dust. We seldom think of the part which dust and smoke have played indirectly in shaping the social habits of the people. How to get rid of dust and fume in the factory, of smoke in the atmosphere, and the incidence of all these on the skin and respiratory organs of man has furnished not only the subject of many a scientific discussion but has stimulated enterprise and encouraged manufacture. In trying to combat their begriming effects we have become a well washed people. The dispersion of these various products has led to the manufacture and use of soap in proportion hitherto unparalleled in the history of man, while these again have indirectly added to employment, wealth and health. Dust and fume begriming agents have therefore done much to socialize mankind, to promote health and to advance civilization for those nations are leading in the path of progress

The Air We Breathe

NINE HUNDRED FIFTY tons of solids per square mile are deposited annually from certain city atmospheres. In the average city air carbon dioxid displaces the life-giving oxygen, and other combustion products interfere with the bactericidal properties of direct sunlight. The larger the town, the more serious such factors become.

Pneumonias, cardiac failure, and many other chronicities have an indirect cause in the prolonged breathing of bad atmospheres. Dust and fumes, therefore, cannot be held strictly as the problem of industry. They are even more complex as problems of public health because their pernicious effects are so often undetected or misconstrued.

Register Company of Dayton, Ohio, has recently made the announcement that their six thousand employees lose, on an average, only 1.5 days per person per year on account of sickness, and this company estimates that every employee-hour saved from sickness was worth forty cents to the company. On this basis they claim a saving of \$120,000 annually because they have been able to reduce their disability rate so far below the average. This striking example of practical results in accident and sickness prevention demonstrates what it is possible to accomplish when careful methods are utilized. The enactment of workmen's compensation laws by practically all of the states renders the prevention of health hazards and

*Address before the Mid-Year Safety Conference, Engineering Section, National Safety Council, Chicago, April 17, 1923.

today whose workers not only require soap and water for themselves but who by the factory dust and smoke they create oblige all of us to resort to similar usage.

Dust is produced or arises from many industrial processes. It is estimated that in the United States approximately four million workers are exposed to the dust hazards. For many years it has been recognized that certain types of diseases occur most frequently among those engaged in dusty trades. The nature of the diseases arising from dust depends upon the character of the dust. In the various industries all kinds of dust are met with. Dusts are generally classified as follows:

(1) Mineral, as quartz dust in mineral mines.

(2) Metallic, as dust from steel polishing.

(3) Vegetable, as dust in cotton mills.

(4) Animal, as dust from fur in felt hat manufacturing.

(5) Organic, as coal dust.

(6) Municipal, dust from streets of cities.

Dust may enter the body by inhalation, through the lungs, by being swallowed with saliva, water or food, and by absorption through the skin. Dusts that are harmful may be spoken of as mechanical and irritative, chemical and toxic, or caustic.

The inhalation of dust most frequently produces an increased susceptibility toward the following classes of diseases:

(1) Respiratory diseases, as tuberculosis, bronchitis, and asthma.

(2) Irritative or inflammatory diseases of the eye, ear, nose or throat, as shown by an undue prevalence of chronic inflammatory conditions of these organs in lime, cement and hair workers.

(3) Dental decay, as shown by the undue prevalence of dental decay among sugar workers.

(4) Skin diseases, as shown by the unusual prevalence of furuncles and eczema in persons exposed to mineral, metallic, sugar, flour and other dusts.

Sir Thomas Oliver, in his book "Diseases of Occupation" has the following to say regarding the amount of dust in the atmosphere:

The amount of dust in the cubic meter of air will vary from 0 mgm. in the clean air of a dwelling house to 175 mgm. in such an industry as felt shoe making. In a dusty trade like cement making, Arens found when no work was being done 130 mgm. of dust in one cubic meter of air and during work when the crushing machines were running 224 mgm. According to Heese a workman following his occupation for ten hours a day would inhale the following quantities

of dust in grams:

	Per Day	300 Days Per Year
Horse hair workers	0.05	15
Saw mills	0.09	27
Flour mills	0.125	37.5
Iron foundry	0.14	42
Tobacco workers	0.36	108.
Chemical works	1.12	336.

A vast amount of research and investigation has been made into the dust problem in industry. The usually accepted view on the subject as expressed by Dr. E. L. Collis is that in general dusts appear to be more injurious as their chemical composition differs from that of the human body or from elements of which the body is normally composed. Thus in the case of lime dust (a normal constituent of the body) notwithstanding its angular form, it is a feeble irritant to lung tissue.

Despite the great amount of research work that has been done on dust and its effects, there still remains much important work that needs to be done on this subject. In making dust counts the "standard unit" is the measurement usually adopted. This term was adopted by the American Public Health Association to distinguish particles of about twenty microns (1/1250 of an inch) in diameter down to the limit of ready recognition under the microscope (about one micron or 1/25,000 of an inch in diameter). But this is not always accurate and there frequently arises error. As yet no definite conclusion has been reached as to the best type of instruments to be used in the collection of dust samples, neither are there definite conclusions as to the sizes of dust particles that are most dangerous to health.

At the present time the consensus of opinion is that the dangerous dust particles are below ten microns, or 1/2500 of an inch in size. This was largely arrived at through work done in connection with studies made of metal miners in South Africa. Post mortem examinations were made, and from specimens of the lung so obtained, were dissolved out the particles of silicious dust. Thus allowing actual microscopic examination and measurement of silicious dust particles found in the lungs.

Realizing the great importance of dust as an industrial health hazard, and in view of the fact that many problems of the effect of dust are as yet unsolved, the United States Public Health Service, through the office of Industrial Hygiene and Sanitation, has begun a comprehensive study of the dust problem in its relation to the effect upon the human body and to the

causation of disease. This study will cover a period of two or three years and will include the classes of dust previously mentioned. The more important points to be covered in this study are:

(1) A study to determine the best methods of collecting dusts of the various classes.

(2) A study from post mortem examinations to determine the measurements of the dangerous particles in the various classes of dust.

(3) A study to determine specific standards and distinctions for the different classes of dusts.

(4) Morbidity and mortality studies to determine the relative harmfulness of different classes of dust.

These studies have already begun on organic dusts at Wilkes-Barre, Pa., and will continue on metallic dust at Meridan, Conn. Studies on the other four classes of dust will be made at four other places. Already the first item has been practically completed and a satisfactory method has been devised for collecting dust samples. There are three usually accepted methods of collecting dust, the Palmer method, the sugar method, and the Konimeter or impinger method. The method that has been developed and that has proven satisfactory is a combination of the Palmer and impinger method.

Fumes, as has been previously mentioned, are the gaseous forms of metals, non-metals and their compounds and also the return of these from the gaseous and solid state. The effects of fumes are largely specific for each substance and it would be necessary to name each special substance in order to discuss the physical effects of various fumes. Obviously, this is impossible. Only a few examples of the more common fumes that cause hazards will be mentioned.

Among the harmful fumes that are found in industry may be mentioned lead, brass, arsenic, mercury, zinc, and other metals, illuminating gas, gases from coal and coke, coal gas, carbon monoxid, carbon dioxid, sulphur dioxid, mineral acids, tar and creosote, wood alcohol, smoke, chlorin, ammonia, naphtha, benzine, gasoline, benzol and many others.

The harmful effects of fumes upon workers depends upon several factors: (1) the amount and length of exposure; (2) the concentration or strength of the fume; (3) the absence or use of protective devices; (4) individual susceptibility; (5) character of fume.—(Continued on page 670)

Health in the Girls' Continuation School of Newark, N. J.

The Findings Leave no Doubt as to the Need of Systematic Health Instruction and Supervision for this Particular Group

By MARY REESOR, M.D., NEW YORK CITY.

IN APRIL 1922 the author was asked by Dr. Geo. F. Holes, director of medical inspection in the Newark schools, and by Mr. Owen R. Lovejoy, general secretary of the National Child Labor Committee to make a study of the health problems of the Girls' Continuation School in Newark, N. J., with a view to determining whether or not systematic medical inspection and health supervision could be carried on effectively under conditions necessarily existing in continuation schools. On the basis of this study it was hoped there might be presented a plan for the development of health work along modern and effective lines which should be especially adapted to meet the needs of the girls in this particular school.

On the health side the needs of the girls in the school in which this study was made, are rather clearly defined. A moment's study of these girls, convinces one that they need training in the fundamentals of personal and civic health. One sees at a glance how lacking they are in normal physical development: how little they know of the joyousness and self respect associated with just being clean and well cared for. One must appreciate the responsibility assumed by a school which these girls are forced to attend even for one half day each week. One realizes anew how in our training for citizenship we do not always appreciate fully the force back of socialized health and normal physical development.

A statistical study was admirably made in this school just a year ago

by Dr. H. H. Mitchell, health agent for the National Child Labor Committee. His findings were presented in an exhaustive report. Dr. Mitchell examined most carefully twelve hundred boys and girls in the continuation schools in Newark. His findings leave no doubt as to the need for systematic health instruction and

on Monday morning, has an acute cold with sore throat, we can advise her as to abortive treatment, but we have no opportunity of seeing her at school until the next Monday morning. Meantime she is left to exercise her own judgment as to whether she should remain at home or attempt to continue her work at factory or shop. Parents depending upon the wages these girls earn, are apt to minimize ailments and urge their daughters to continue work if possible.

Much can be done to meet this situation if both doctor and nurse are present to supervise daily inspection, to maintain a carefully planned follow-up system, and to obtain closer co-operation between school and employer. Acute illnesses could thus be detected and followed up in homes and factories.

(2) These pupils have little time at their disposal.

In order to visit a clinic or hospital to which she may be referred by the examining physician, a girl must either utilize her half day regularly devoted to school work or she must ask her employer for "time off."

At the school we gladly grant permission to the girls to use school time for this purpose. If, however, the clinic to which she is referred is not held on that particular half day she attends school, we cannot be of much assistance to her.

(3) Definite health standards have not been established for pupils in this type of school.

When a girl is examined for her working papers, she knows she must obtain dental care if the examining physician or nurse recommends it. If she disregards these recommendations she knows the desired working papers will be denied her. When the work-

Where the School Girl Works

OF ALL the children in the United States 346,610 girls, or 5.6 per cent, were reported by census enumerators as gainfully employed in 1920. Of the working children, both boys and girls, 17.5 per cent were employed in manufacturing and mechanical industries, the highest percentage in non-agricultural pursuits being employed in the New England States.

Age, educational, and physical standards vary because regulation is a function of state rather than federal legislation. Practically the only regulation of many types of child labor results indirectly from the operation of the compulsory school attendance laws. Hence the significance of any study of health conditions in this group.

supervision in continuation schools.

With these needs definitely enumerated there appeared at once certain handicaps to the carrying on of systematic health work in a school of this unusual type.

The following enumeration of these difficulties may serve to make plain to those not intimately acquainted with the conditions, the complicated problems presented for solution.

(1) The pupils in this school attend school but one half day each week.

If, for instance, a girl examined

*Condensed from the Original Report of survey of health conditions in the Girls' Continuation School, Newark, N. J.

ing papers are obtained, she enjoys a refreshing sense of independence and she frequently exercises this new possession by resenting further health interference.

This is entirely the result of ignorance. If an interested doctor will spend one hour examining these girls, he will be convinced that they are ready and willing to be taught. They respond with true enthusiasm when they are convinced that the doctor has something worth while to tell them.

It is true that they are not interested in a formal physical examination. Here is where the educational health work counts. No doctor can rush girls through a hurried routine examination, with his eyes on the clock, fearing that he has given more than the allotted five or ten minutes to each girl, and expect to get results or to elicit interest or cooperation from the girls under examination.

Such formal, routine examinations are useless in any school, but in the type of school with which we are here dealing, they are positively harmful. They give these ignorant, dependent girls an entirely wrong idea of what health education means.

The first days we examined at the Girls' Continuation School in Newark, the girls feared the examination. If a girl were told when to present herself for examination, we discovered she found some excuse for being absent from school that half day. After a few days, as the girls who had been examined told other girls about it, this feeling of fear disappeared. When it was announced in the rooms that on a certain day the doctor would see the girls who wished to talk over with her problems relating to their health, the examining room and corridor outside the room were filled with girls waiting "to see the doctor." They brought to me their personal secret problems and asked for help in their solution.

Sickness Does Not Pay

Fortunately, employers are beginning to realize that the sickly employee is not a paying proposition. He knows that it pays to investigate the health as well as the working papers of the girls on whom he depends so largely for his gains. Employees are beginning to realize that they must measure up to certain health standards or their places will be filled by those more physically fit.

There will always be a certain number of industrial girls who will have to be forced into hygienic living through fear of "losing their jobs." While this may not be one of the

highest health ideals, it is nevertheless, a very helpful one in helping us bridge the gap between cure and prevention.

(4) Follow-up work in this type of school is difficult.

The girls in this school come from many different parts of the city and from various neighboring towns. This wide distribution is what makes the problem of follow-up work a very difficult one.

This school is extending its work and influence into the homes with definite good results. The teachers in the school are visiting places of employment and studying the conditions under which the girls work. The school nurse is visiting homes, advising and helping parents, studying home conditions and striving in every possible way to improve the living conditions. The nurse visits clinics and gets reports of examinations. She calls upon private doctors and obtains data on past illnesses of the girls when such data is needed by us in planning a health program.

If a department of home and factory visitation can be organized and administered efficiently much good will surely be accomplished.

It was evident that in the few weeks at our disposal, we could examine only a small percentage of the two thousand girls attending the school.

In order to obtain findings in a representative group, selection for examination was made:

(1) From the class made up of the highest type of girl the school afforded and from the class composed of girls who physically and mentally represented the lowest type in the school.

(2) From girls selected for perfect attendance and high class records and those with poor attendance and low class records.

(3) From girls selected who were just entering the school and those ready to leave the school.

(4) From girls employed in factories and shops and those working in their own homes or working out as mother's helpers.

(5) From girls with good home environment and those living under the most unhygienic surroundings.

(6) Finally we permitted the girls to volunteer for examinations. There appeared in this group, girls who said they were perfectly well, those who were acutely ill, and others who thought they were not as well as usual.

In all, two hundred examinations were made.

As a result of these examinations we found that the health needs of these girls fell easily into three general groups: (1) hygienic; (2) orthopedic and postural; and (3) nutritional.

Examination Findings

Of the 200 girls questioned, 10 per cent bathed every 2 or 3 months, 25 per cent bathed every month, 60 per cent bathed at indefinite periods, 5 per cent bathed once a week and no one bathed daily. While at first it seemed incredible that in a crowded city, girls could bathe so infrequently and yet remain members of society, findings verified their statements. Some of the skin conditions found were indescribable. Stripping the girls to the waist revealed conditions which astonished even the principal, who has been associated with these girls since the opening of the school. Only 5 per cent were found to have well cared for skin. About 12 per cent of the girls had acne. To our surprise not a case of scabies was found, although we were told by one of the nurses in a continuation school in New York City that the control of scabies was one of her most perplexing problems.

The greater number of the girls arrange their hair simply. Many of the girls have their hair bobbed. The nurse and teachers have been waging war against pediculi, evidently with fairly encouraging results: 75 per cent were found to have nits; 33 per cent were found to have pediculi. Four months ago 90 per cent of the girls had nits and 50 per cent had pediculi. Of those who have pediculi now, practically all are girls just entering the school.

Although the girls had had their teeth examined and supposedly cared for before receiving their working papers, we found a surprising number of girls in need of dental care—about 35 per cent of those examined.

Many of the girls have never possessed or used a tooth brush. Few of the girls seem to appreciate the close relationship of a clean mouth to good health.

Nails were found to be uncared for in ninety-five per cent of cases. Girls working with furs, tobacco, copper wiring, etc. were found in a number of cases to have infection about the nails. Many of the girls bite their nails and have little appreciation for the teaching that unclean fingers should be kept out of the mouth and away from the face.

A few of the girls apologized for conditions and confessed they never wash their stockings. They wear them

until they wear out. None of the girls have had instruction in the hygiene of menstruation.

On warm days body odors were especially offensive. A few of the girls attempted to counteract these odors with highly scented talcum powders, others seemed not to be sensitive to the situation and failed entirely to see the social problem involved. Many of the girls said they would bathe if there were facilities for doing so in their homes. We appreciate the force of this argument but labored no less earnestly to make them see that a fairly satisfactory bath may be taken with a pitcher of water in an ordinary basin. We referred them to the public baths and numbers of the girls have reported to the nurse that they have gone to these bathing places and are having at least one bath each week.

Class room inspection is resulting in improved conditions of the hands and hair, and class room instruction as to the care of the body, underwear and stocking, etc., is resulting in a cleaner and more wholesome school room atmosphere.

In judging and advising these girls we must keep constantly in mind the conditions under which they live and work. It is to be remembered that many of them are foreigners with ideals very different from ours. It is a simple matter for us to tell girls they should drink milk, eat green vegetables and fresh fruit. We do not always realize that many of the foreign mothers provide nothing but coffee for their children to drink, and scores of them never cook a green vegetable. It must be a matter of educating the children through the school, and the parents through the children.

In no part of the examination did the girls seem so much interested as in that of posture. These girls do not like to be told they have conditions which detract from personal charm and attractiveness. A hollow chest with prominent clavicles, does not appeal to the girl rejoicing in the thrills of wearing low necked evening gowns to dances. Little does she care how many decayed teeth she has in her mouth if her lips are properly rouged or how unclean her body is if she is coated with a covering of highly scented talcum powder.

Of the girls examined 18 per cent have weak feet. Many of the girls have bunions, corns and other deformities due to wearing ill fitting shoes. None of the girls complained of pain in the feet though many of them stand all day at their work.

Considering the relation of weight

to age and height, we found that 7 per cent of these girls were not more than ten pounds under weight, and eight per cent not more than 10 pounds over weight. We appreciate the fact that weight is only one of the factors involved in the consideration of nutrition of an individual, yet in studying girls over whom we have so little supervision it must serve as an important criterion.

Many of these girls eat nothing in the morning. They get up late and have to hurry to shop or factory. Others drink two or three cups of black coffee and eat a piece of bread or cake. Comparatively few have cereal or eggs for breakfast. At the luncheon hour they are either not hungry or do not care to eat in the unclean places provided for them. Many of the girls do not bother to carry lunch from home. They sometimes eat a piece of cake or drink a glass of soda water. At night they eat whatever is provided or what appeals most to them. Few of the girls seem to realize that what they eat bears a direct relationship to what they can do. The idea of eating to live has not functioned with them. Considering everything, these girls are surprisingly well nourished. They seem to thrive in spite of and not on account of what they eat.

Miscellaneous Conditions

Certain conditions which do not fall directly or conclusively under any one of the headings in our classification of defects, may be noted as follows:

Tuberculosis is difficult to detect during the typical superficial school examination unless there are definite lesions with accompanying frank symptoms. Two per cent of the girls examined were classed as suspicious. These girls were referred to a special clinic for further study.

In the three cases of definite organic cardiac involvement which were noted, compensation was fairly good. These girls were conscious of heart conditions though they had not been told by a doctor that their hearts were affected. They realized they could not run for cars, climb stairs, or take long hikes. With care they go about their work with little discomfort. They were referred to a cardiac clinic for further examination and treatment.

In 15 per cent of the cases examined the thyroid was found to be slightly enlarged; in 4 per cent markedly enlarged. In only one case was the enlarged thyroid gland accompanied by cardiac and tremor symptoms. This girl is under the care of

a private physician for the condition.

A number of girls have had tonsillectomies performed as the result of recommendations made at the time they were examined for working papers. We find that 20 per cent of girls examined had slightly enlarged tonsils, and 10 per cent had markedly enlarged tonsils with attending symptoms and abnormalities. These girls have been referred to clinics, hospitals or private physicians for care.

Four per cent of the girls examined have not yet menstruated; 5 per cent have had menostasis for periods varying from six weeks to three months; 10 per cent have had dysmenorrhea at times.

Considering the fact that these girls are between 14-16 years of age these slight variations from the normal seems insignificant.

Five per cent of the girls have defective vision. In nearly all cases of defective visual acuity, glasses had been obtained before the working papers were granted. Many of the girls do not wear their glasses as directed.

It seems apparent from the present study that if efficient health work is to be carried on in this school there must be proper and adequate equipment for the work, and an organized system of health education, based upon a simple practicable health program.

The physician is named as the most important part of the equipment because this arrangement shows the logical relation of the physician to this entire project.

We do not undervalue the routine examination, but we do feel that too often the entire procedure is mechanical, hurried, and lacking in the human note and contact so necessary in the process of health education. These girls must be taught as well as examined.

The physician who undertakes this work should be genuinely interested and should have faith in it. He should possess a personality which will inspire the confidence of the teachers and pupils in the school and which will promote a fine spirit of cooperation.

In the carrying on of health work, the value of a well trained, interested, efficient nurse can scarcely be overestimated. She is the link between the doctor and the school; between the school and the home. It is she who makes it possible for the medical examination to function in the lives of the girls who are examined.

The examination room need not be a large room, and elaborate equipment is not necessary. It should be light, airy, and—(Continued on page 652)

Reaching Workmen as Citizens With the Safety Idea*

St. Louis Reduced Street Car Accidents by 56 Per Cent, Deaths by Steam Railway Accidents by 60 Per Cent, and Fatalities from Industrial Accident by 86 Per Cent Over a Period of Five Years

By C. W. PRICE, PUBLIC SAFETY DIVISION, ELLIOTT SERVICE COMPANY, NEW YORK CITY.

IN ST. LOUIS, during 1917 one hundred ten workmen were killed by industrial accidents; in 1922 only fifteen were killed, although the actual number of workmen employed had materially increased. Industrial managers will naturally ask the question "How was this accomplished?" If you should ask any one of a hundred industrial managers in St. Louis he would tell you that in part it was accomplished through the intensive educational effort along safety lines made in the individual plants, but in a much larger part it was accomplished through a community safety campaign.

What has happened in St. Louis is happening to many industrial centers. Employers of labor are beginning to see that when their workmen are reached outside of the plant and become interested in safety in the home and on the street, they return to the plant not only interested as employees but, more important, convinced as fathers and as citizens of the value of safety to them and their families.

The first important step in the accident prevention movement in this country was the discovery that safety can be organized in an industrial plant through a continuous campaign of education, and that a reduction of from 75 to 90 per cent in deaths and serious injuries can be effected. The second great forward step—and this was made within the last five years—was the discovery that community safety has a vital bearing on industrial safety; that it is indispensable to the final solution of the industrial accident problem.

Industrial managers are now interested in community safety not only because it helps the safety work within the plant but because it insures them against the loss of the services of their workmen because of death or serious injury outside of the plant. For instance, in 1920 the Ford Motor

Company of Detroit with fifty thousand workmen lost one workman during the year on account of an accident within the plant, while ten valuable workmen were killed and several hundred were seriously injured outside of the plant.

Traffic Safety

Employers of labor are also vitally interested in traffic safety because of the number of commercial vehicles which they have constantly traveling on the streets and because of the increasing cost of public liability insurance. This new effort among employers of labor to extend the safety campaign beyond the walls of the factory and reach the workmen in their homes is in line with the recent development of the whole industrial relations movement which extends its effort beyond the plant to interest the workmen in matters of thrift, health, education, and Americanization.

The question is, "can safety be organized in a community with a continuous year-round campaign of education as it has been successfully organized in the large industries?" That it can be done is evidenced by the records of St. Louis, Milwaukee, Washington, and other cities. Comparing the records of St. Louis in 1917 with the record of 1922, deaths from street car accidents were reduced 56 per cent, deaths from steam railway accidents were reduced 60 per cent, industrial deaths were reduced 86 per cent, and deaths from automobile accidents were reduced from 32 to 13 per 10,000 machines, or the records of the reduction in automobile accidents is especially significant when we consider that during the last five years the number of automobiles in St. Louis increased from 24,000 to 92,000.

In 1920 the Milwaukee Association of Commerce organized a safety bureau and during the next two years as a result of their efforts, accidental deaths from all causes were reduced 24 per cent, and deaths from automobile accidents were reduced more than

50 per cent. Washington, D. C., has set a new high record of achievement during the first few months of its permanent safety campaign. Following a successful safety week in November, 1922, the Washington Safety Council was organized and began to function February 1st, 1923. During February and March accidental deaths from all causes were reduced 32 per cent as compared with the record for 1922, traffic deaths were reduced 43 per cent, and deaths to children were reduced 85 per cent.

A careful study of the experience of these three cities and some dozen other cities in which community safety has been successfully organized reveals the significant fact that there are three determining factors which are largely responsible for the success in reaching all of the people and inducing them to stop being careless and to begin being careful. These three factors are: Systematic daily safety instruction in the public and parochial schools, a continuous poster campaign on the streets, and an intensive educational campaign in the daily press.

Safety Education

One-half of all that can be done in any community to reach the adult population will be done through the safety education of school children who carry the safety message home to their parents. This is the testimony of the men who have been most active in cities where successful safety work has been conducted.

In 1918 Dr. E. George Payne, then the director of the Teachers' College in St. Louis, developed a plan of safety instruction which has proved so successful that since that time it has been adopted in thousands of schools over the country with remarkable success. Dr. Payne who is now professor of education at New York University will send the details of this plan to any one on request. The secret of the success of this plan lies in the fact that it does not call for an

*Read before a joint meeting of the Board of Trade and the Transportation Club, Louisville, Ky., June 4, 1923.

additional study in the already overcrowded curriculum, but rather it provides for the use of safety materials in each of the studies already included in the curriculum and provides for safety committees in each school room, thus making safety an active and vital part of the child's daily life.

The second determining factor in a successful community effort is the visualization of safety on the street. The one difficult problem in any safety campaign is to sustain the interest of the public day in and day out through the year. This can only be accomplished by visualizing safety so that the driver or the pedestrian at every turn will be reminded of safety. Washington during the past three months has worked out the first successful plan of accomplishing this through a continuous poster campaign. Slogans with a punch and a grip, a different one each month, are printed on large posters and displayed at the street intersections, at filling stations, on street cars, busses and taxicabs, in all school houses, public buildings and at entrance to factories. The first poster read:—"The Reckless driver is a criminal"—the second—"The Jay Walker is Taking a Short Cut to the Hospital"—and the third—"Better Be Careful than Crippled."

The effectiveness of the poster campaign in arousing public interest and reducing accidents is evidenced by the following statements made by three prominent citizens of Washington:

Mr. William E. Ham, president, Washington Railway and Electric Railway Company and president of the Washington Safety Council, said:

The continuous poster campaign conducted in Washington has proved to be one of the most effective means of reaching the public and obtaining their cooperation. It has already assisted in producing a good accident reduction in the past three months.

Mr. J. J. Boobar, vice-president and general manager of the Yellow Taxicab Company and president of the National Association of Taxicab Operators:

Results and my personal observation satisfy me that the plain marking in white of street crossings and safety zones, and the display of posters with a punch at congested street corners and on street cars, taxicabs and trucks is the most efficient means of minimizing street accidents, and carrying a lasting and impressive message to the pedestrians and the drivers.

Majors Sullivan, Superintendent

of the Metropolitan Police:

The safety poster campaign, more than any other single activity, has helped the police department of Washington to curb recklessness and carelessness on our streets, and in two months had assisted in reducing the total number of accidental deaths 32 per cent—traffic deaths 43 per cent and deaths of children 65 per cent.

The newspapers must be named as

Milkmen of Costa Rica

Cleanliness is only relative. The dispenser of foods needs to hamper himself by sanitary methods only to an extent demanded by the purchasers of his wares. In sub-tropical climates the preservation of milk is difficult and the milkman distributes his product within a very small radius from the point of production. Picturesque these Costa Ricans are, but dipped milk would find small market in America.

the third most effective medium through which every home can be reached daily with the safety message. The newspapers can play an important part in building up in the minds of the people a new interest in safety and a new sense of their obligations to cooperate in saving human life.

In every community, however large or however small, safety instruction in the schools, the poster campaign on the streets and the continuous educational campaign through the newspapers can be conducted with equal success and at a nominal cost. The demand everywhere is for definite information regarding ways and means of conducting such a campaign and materials to use in carrying out the program. Such material is now available, including not only specific instructions in regard to the organization and the conducting of the campaign, but complete material for the use of teachers in teaching safety, posters suitable for an entire year's campaign and suggestions, and specific articles for use in the newspapers. This material prepared by men of national reputation and based upon wide experiences in many cities, makes it possible for any group of citizens to successfully organize and conduct a community effort.

Dairy Products Exports and Imports

That the United States is reaching the point where its imports and exports of dairy products almost balance was pointed out by H. E. Van Norman, president of the World's Dairy Congress Association, in an interview dealing with the general international dairy situation. The World's Dairy Congress, for which he is preparing, will be the first world dairy meeting to devote as much attention to the business and economics as to the science of dairying. It will hold its opening sessions at Washington, D. C., on October 2 and 3, 1923; spend a day at Philadelphia, Pa., where the National Dairy Council and the Philadelphia Inter-State Dairy Council will demonstrate their methods of promoting health by educating the public as to the food value of milk, and continue at Syracuse, N. Y., in cooperation with the National Dairy Exposition from October 5 to 10. Mr. Van Norman said:

"The United States has reached a point where the production and consumption of dairy products are almost equal, as is indicated by the fact that its exports and imports of dairy products nearly balance. For several years we have been exporting large quantities of condensed milk, chiefly to the war stricken areas, and we have always imported considerable foreign cheese; so a more careful distribution of our productions would not eliminate our foreign trade in dairy products, even though our production and consumption actually attained a balance.

Red Cross First Aid Railway Car

The American Red Cross is reconditioning for service their first aid railway car. This service was carried on from 1910 to 1917 when it was temporarily discontinued on account of the concentration on war work.

Two surgeons and their assistants accompany the car, one giving full time to the railroads and the other giving most of his time to the Red Cross chapters visited on the various trips. The car is fitted with living accommodation for the staff and a lecture room accommodating fifty persons. The car carries emergency equipment and a reserve supply of food. In case of disaster it can be quickly converted into a thirty bed hospital. (*Red Cross Courier*, June 2, 1923, 2, 22.)

Physical Education on Playgrounds, Limits and Opportunities

When Formal Gymnastic Work Was Taken Out of Doors, It Underwent Complete Transformation and Correctional Work Has Been Replaced by Recreational Features

BY C. E. BREWER, COMMISSIONER, DEPARTMENT OF RECREATION, DETROIT, MICHIGAN.

THE limitations and opportunities of physical education present such a vast field for discussion that it is impossible to cover the whole field within a brief space. The preponderance of argument lies on the side of opportunities for physical education on playgrounds provided facilities are adequate. The opportunities may be divided into three general classes, physical, social, and psychological.

Physical Advantages

Every physical educator knows the metabolic and katabolic process of the human body. The oxidation of food furnishes body energy. The living protoplasm is broken down and built up through chemical changes of muscular tissue. The energy exhibited by a contracting muscle is derived from the oxidation of the fuel substance within it. Oxidation is dependent upon good lungs and good blood circulation to carry the oxygen to where it is needed. Consequently, physical exercises increase lung capacity, which in turn increase circulation, which in turn stimulates oxidation resulting in greater energy, which needs more oxygen to maintain its rate of speed or exercise and so the cycle goes around again.

Social Opportunities

Increased muscular stamina, endurance, better health, and nervous response or reaction would result from exercise under proper and wholesome conditions. This in turn, results in

bodily skill, alertness, precision, graceful and easy body carriage, all of which are necessary for social development.

First, the educational features, which are social in nature, must not be overlooked. Every game, every exercise, has an educational value. We all must learn to exercise our limbs, our senses, and other body muscles, before we learn to think, as they are the instruments of our intelligence. It is to be regretted that the playground and recreation workers, also physical

body is the most important phase of a man's success and that is what our profession is most interested in—making a success of the material or people, with whom we deal. A person whose mind does not control his body is a degenerate and a parasite on society. Muscular action is dependent upon nervous response. If we have the proper nervous response to the impulses or volition, the proper muscular reaction resulting in the muscles executing the wishes of the mind. This discipline of mind

Correctional features of exercises and games are emphasized in this children's group. Though correctional work is of necessity more or less individual, improvement is hastened when the element of play lightens the burden of formal training. And it is more effective in the open.

educators, overlook or lay very minor emphasis on the educational value of games. Through games and exercises, the participant learns team-work, loyalty, cooperation, sportsmanship and other fundamentals of citizenship, which are so essential to the future business man. Every successful business man has had to learn the value of team-work, loyalty, and cooperation before he becomes a success in his chosen field of endeavor. The degree of success depends upon his attitude of mind or the psychological aspects of recreation.

The discipline of the mind over the

over the body, results in coordinated actions and self-control. Self-reliance is developed, resulting in quickness of thought and action so essential to a successful business career. There is no question but that better morals are coordinated with a clean mind and body. If the restrained impulses are pent up and denied expression, they may explode into some form of excess or vice; but if expressed in clean wholesome play or recreation, a better and more contented class of citizenry will be the reward of the faithful physical educator or recreation worker, who has the ideals of the profession.

The advantage of mass athletics or calisthenic work on a playground should not be overlooked, as a larger number can be taken care of than in other forms of team games. Exhibitions, drills, and pageants make big special features of any city's recreation program and the publicity value of these spectacular events must not be overlooked. Physical education and

recreation workers must sell their program to the community and taxpayers—sell or advertise his product to the consumer.

The correctional feature of exercise and games in the open air from a health viewpoint is an opportunity which must not be neglected. Our last draft for the World's War clearly demonstrated that correctional work is needed by nearly 70 per cent of the adults. The place and time to do this is in the gymnasium or on the playground during their youth and then one should continue to keep in "trim," by participating in some form of physical recreation during his adult life.

The limitations can be more briefly and concisely stated, yet they are important and vital.

Formal gymnastic work on a playground has no place in the minds of the children and adults on most play grounds. It depends upon the nationality of the community in which the playground is located. Where turnvereins, sokols and other gymnastic societies exist, the adversion is not so marked as in other communities. Children, as well as adults are antagonistic towards formal work. The child objects, probably because he has so much of it in school. The adults—because there is too close a resemblance between calisthenic work and the machine-like methods of our present day specialized form of employment. One wants to be away from all machine-like procedure and be free and spontaneous. Unfortunately, we are taking our recreation passively instead of actively. We have become affected with "motion-picture-show-itis" and "bleacheritis."

Then too, there is a general lack of facilities to engage in formal work upon the majority of playgrounds. There are no lockers or locker rooms where one can change his civilian clothes to a gym suit, no showers available after a "sweat-up"; the boiling hot sun, dusty playground with a cinder or gravel surface are not conducive factors for participation, particularly where the element of competition is lacking.

The social features are lacking in formal work as there is a feeling of individualism, rather than of team work, particularly in apparatus work and calisthenics, whereas in games of skill—cooperation, team spirit and team play are highly developed. In

The educational value of games lies chiefly in the discipline of mind over body, but the social qualities of team-work, loyalty, cooperation, develop along with interest in the sport.

apparatus work, the period of idleness, i.e.—while one is waiting his turn to perform—gives only a minimum of exercise for a maximum expenditure of time. While waiting ones turn on the apparatus, the interest of the participant is lost and the group wanders away to take part in a game where there is more action.

These are only some of the questions of the opportunities and limitations of physical education work on the playgrounds. Much more could be said in detail, but lack of time forbids. There is no question but that formal physical education work has a place in the program of a playground—just how big a part is a debatable question. Just as the attempt to take formal gymnastics out of doors, back in the 80's of the past century, resulted in the establishment and development of our modern playground system—so the modern physical education and recreation work has resulted in the increased interest of girls and women in athletics. Whether this is a good thing or not remains to be seen. The only advice worth while is the old saying, "Circumstances alter cases." What applies to one playground, one community or a city, may not apply or be feasible or practical on another playground, or in another community or city. All angles of the problem must be gravely considered in arriving at either a negative or affirmative decision to include or exclude physical education work in a playground or recreation program.

Physician Summoned by Radio

The steamship West Cahous, lying at anchor in Baltimore harbor, about nine miles from the city, needed medical help at about 3 a. m. recently

and needed it quickly, says the U. S. Public Health Service. A member of the crew had fallen into the hold and had hurt himself seriously. So the captain of the ship sent a wireless broadcast asking help.

The call was picked up, not in Baltimore, nine miles away, but at Cape May, N. J., about a hundred miles due east of Baltimore. As Cape May was separated from the West Cahous by parts of New Jersey and Delaware and by the eastern shore of Maryland, not to mention Delaware and Chesapeake bays, no direct help was possible.

But the operator was on the job. Promptly he consulted the long distance list in the Baltimore telephone directory and called up the residence of the Public Health Service, surgeon in charge of the Marine Hospital in Baltimore—one hundred miles to the west. The surgeon, roused from sleep to receive the message, asked him to radio certain emergency treatment to the West Cahous and to direct the captain to send a boat to a certain pier in Baltimore, where he would find a surgeon waiting to go out to the ship with him. And so, in the middle of the night, in less than an hour, a wireless-controlled sea-going ambulance reached the side of the injured sailor and brought him to the hospital.

How Athletics are Influencing Dress

Henry D. Curtis, writing in the *Physical Education Review*, expresses as the ideal in dress that it "shall hamper physical activity and the circulation as little as possible and that it will not, through its concealments, remove all incentive to physical perfection." If we might bring our little girls up to wear knickerbockers, we should find that many of the ills from which women suffer would disappear, he says. This movement has already gone further than many of us realize as in some of our western normal schools, practically every young woman appears in trousers on Saturday, and almost no hikes or outings are taken in any other costume.

It is estimated that seagulls in and around New York harbor are effective as scavengers to the extent of serving to dispose of about two hundred and eighty tons of offal a day.

Clean Teeth Not Always Sound*

Preventive Dentistry Takes Account of Prenatal Influence of Mother's Diet and Nutritional Balance During Early Years as Real Factors in Dental Decay

By DR. HAROLD DeW. CROSS, DIRECTOR, FORSYTH DENTAL INFIRMARY FOR CHILDREN, BOSTON, MASS.

INVESTIGATION has shown that 96 per cent of the children who come to this country from the southern part of Europe have sound teeth, while it is well known that the teeth of 96 per cent of American children are defective. Strange to say, too, the vast majority of the foreign children never knew what a toothbrush looked like until they entered American schools.

Good teeth are determined before a child is born and the chances are, even without the use of a toothbrush, teeth that are originally sound and well constructed, will remain sound for many years. The toothbrush does not make good teeth. They are developed the same as any other part or organ of the body, and if they are not well constructed and sound, it will be found that the use of a toothbrush until doomsday will not save them from inevitable decay.

Prenatal influences, proper diet, including coarse whole foods—milk, leafy vegetables, and fruit are the things that make good teeth, not the use of the toothbrush, however child should have the right diet before the birth of her offspring and the child should be breast fed a suitable length of time rather than fed upon any kind of prepared milk or other foods. This makes a great difference in the state of the teeth of a young child.

Herbert Hoover says: "If we could grapple with the whole child situation for one generation, our public health, our economic efficiency and the moral character, sanity, and stability of our people would advance three generations in one."

We have been taught to believe that dentists have much to do with good teeth. The work of the dentist, however, only begins after the teeth are

here, when they are all formed and in whatever condition they are developed in the jaw, which is the result of the prenatal influence, whether good or bad, so far as the teeth are concerned.

We may consider that there are two kinds of dentistry, preventive or public health, of which little is known or practised, and which has to do, principally, with children; and regular, reparative, or technical work, which deals with children over six years of age or with adults. So far as children

are very necessary and also as much care and attention in regard to diet and hygiene should be given when the child is from two to five years of age.

The sixth year in a child's life divides the preventive and reparative care necessary and the limit should not be reached before this care is given. Care in the kindergarten age is better than when in the first grade at six years, and the nursery or pre-school time is better than the kindergarten. So, too, prenatal care is better than the nursery age and is the best and only time to fully realize the importance of primary teeth, and lay the foundation for good and sound permanent teeth.

All adult dentistry diseases, except pyorrhea, are the result of poor tooth development or neglect of the proper diet and hygiene during childhood. Dead teeth, local infections and diseases of the heart, kidneys and joints are the results of childhood neglect of the teeth and, if caries could be eliminated, would prevent all these later complications.

So, use the toothbrush, but do not depend on it as the savior of your teeth.

Mothers, before the baby comes, must take the responsibility of giving good or bad teeth to their offspring and before six years of age, the whole question of good teeth for life will have been decided.

Sleep in Churches

The *Lancet* reports the Bishop of Durham as making a public appeal for better ventilation in churches, stating that in his opinion the ventilation of parish churches tells more directly on the efficiency of the ministrations of the clergy than many other circumstances apparently more relevant, while inattention and restlessness on the part of the congregations result primarily from the breathing of a vitiated atmosphere.

Underwood & Underwood
By all means for ethical reasons teach the toothbrush habit to children who have not acquired it at home. It is far more important, however, that they get lime, mineral salts, and vitamins in their foods to build their bodies with.

are concerned, public health dentistry deals with diet, general and dental hygiene, and prenatal influences. Reparative dentistry has been practically a failure so far as reducing caries is concerned and children still arrive at the first grade in the public school with teeth as bad as if no work had been done for older children. Caries is increasing with children, two-years old, kindergartners, and first graders. We need the art of reparative dentistry, developed as it is to a very high degree of skill, for all those too old to be benefited by preventive dentistry, and that means all over six years of age.

It has been said that a clean tooth never decays, but the teeth must be sound in the beginning to make this true. Prenatal influences and care

*Read before the Massachusetts Health Conference, Springfield, Mass., April 26-28, 1923

The Health Examination Movement

The Examination Advocated Is a Medical Appraisal of the Individual to Ascertain Physical Impairments and Faulty Habits, With a View to Their Correction

By JAMES A. TOBEY, ADMINISTRATIVE SECRETARY, NATIONAL HEALTH COUNCIL, NEW YORK CITY.

PERIODIC physical examinations of all persons have been recommended by progressive sanitarians for many years. The original suggestion, in fact, seems to have been made more than half a century ago, but only within comparatively recent years has the movement received considerable impetus and developed the momentum which promises to make it a real and important factor in the physical welfare of the nation. The movement is not novel, but the present organization of it on a national scale, a task now undertaken by the National Health Council¹, is a new and culminating development.

History of Movement

Before going into the whys and wherefores for health examinations, a brief description of the genesis and evolution of the movement seems worth while. Periodic examinations for life insurance companies were suggested about 1870 by a Dr. Dobell in England, and Dr. Bares, a French hygienist, urged them some twenty years ago, though there is no record of either of these recommendations having been adopted at the time. In April, 1909, Dr. Burnside Foster submitted to the Association of Life Insurance Medical Directors a definite plan of life conservation, which included a recommendation for periodic physical examinations every five years. The Provident Life Insurance Company, of which Dr. E. L. Fisk was medical director, was the first to adopt this plan for its policy holders and did so later in the same year. In 1911, Mr. H. J. Messenger, the actuary of the Travelers Insurance Company, urged life insurance companies to take up these measures. In 1914,

Dr. S. S. Goldwater, commissioner of health of New York City, announced the establishment of the system among the employees of the city health department. The late Dr. H. M. Biggs, commissioner of the New York state health department, also advocated such examinations for a dozen years.

Health examinations in industry began about 1913 in which year Dr. W. Irving Clark published a paper on the subject in the *Journal of the American Medical Association*. The following year Drs. H. E. Mock and J. W. Schereschewsky reported on results of examinations in industry. Physical examinations for the general public have actually been offered on a self-supporting business basis since 1914 by the Life Extension Institute. This organization was first proposed by Mr. Harold A. Ley, who interested a number of prominent persons, including General Gorgas, Mr. Taft, H. P. Davison, F. A. Vanderlip and Charles H. Sabin, who consented to serve as directors.

During the last decade, many other agencies, such as health departments, life insurance companies, hospitals, clinics, industrial concerns, and individual physicians have been taking more and more interest in the proposition. Finally, the American Medical Association, representing the organized medical profession of the country, went on record in 1922 and again in 1923, as favoring periodic medical examinations of apparently healthy individuals. The next step is for the National Health Council to achieve nation-wide success in its health examination campaign.

What is a Health Examination?

The National Health Council advocates "health examinations." A health examination is a thorough medical appraisal of the human system to detect physical and mental impairments and faulty habits of hygiene. Dr. T. Ordway has called it a medical survey, one which is "a systematically arranged record of facts pertaining to the individual to serve as a stimulus and guide for his improvement." Dr.

Louis I. Harris calls it an audit of the physical assets and liabilities and says, "This is the most important and necessary next step in private medical practice as well as in public health work." Dr. Roger I. Lee says that the best thing about such a health examination is that it shows when a person is healthy. He states that it should fulfil three requirements: (1) detection of organic pathology, to be followed by correction, compensation, or control of lesions; (2) detection of non-organic functional disturbances, to be followed by correction; (3) evaluation and classification of each individual as an entity, followed by directions as to suitable future activities.

The reasons why health examinations are beneficial are so obvious that hardly any argument for them is necessary. They are, of course, advantageous to the individual in that they serve to detect the beginnings of organic disease, or to discover the existence of definite physical impairments, of which the person was unaware. Faulty personal habits of living, errors of hygiene, and possible shortcomings in environmental conditions are frequently brought out. For instance, routine examination of freshmen at Harvard College shows that about 80 per cent have had mechanical use of the body, or faulty posture. Over one-third of this 80 per cent had very bad mechanical use. These faulty postures are generally habits and not defects. As an administrative function, health examinations form an excellent method of health education and help to raise the too low standard of national vitality by bringing to light and assisting to correct physical defects of the population as a whole.

Evolution of Public Health

But there is a still more potent reason why the health examination movement is one of the next steps in public health. It is because public health has about reached that stage of development where personal hygiene is getting to be more important than control of one's surroundings, includ-

1. The members of the National Health Council include: American Association of Industrial Physicians and Surgeons; American Child Health Association; American Public Health Association; American Red Cross; American Social Hygiene Association; American Society for the Control of Cancer; Conference of State and Provincial Health Authorities of North America; Council on Health and Public Instruction of the American Medical Association; National Committee for Mental Hygiene; National Committee for the Prevention of Blindness; National Organization for Public Health Nursing; National Tuberculosis Association; United States Public Health Service; and Women's Foundation for Health.

ing in that term both inanimate objects and other human beings. As the public health movement has progressed, sanitary science has triumphed over environmental conditions and, broadly speaking, over many of the communicable diseases. The sanitary engineering phase of public health in which pure water supplies, effective methods of sewage disposal, sanitary production of milk, eradication of insect-borne diseases, improvement in housing, and similar engineering functions, so highly developed under the guidance of such authorities as the late Professor W. T. Sedgwick, has reached the point where now it is usually a matter of routine. Of course, much remains yet to be accomplished, especially in the rural districts, but the field has been well tilled. The seed has been sown and cultivated, the plant well nourished with here and there a barren spot, perhaps, but the harvest is already for the gleaning. Such diseases as typhoid fever are definitely on the wane; the death knell has been sounded for hookworm, malaria, and yellow fever. Diphtheria is being conquered, with now and then, nevertheless, an attempted rally. Man has vanquished smallpox, though this insidious foe is ever watchful for the time when carelessness, apathy, and ignorance may release it to ravage again. The venereal diseases have been recognized as health enemies as well as moral ones; tuberculosis is losing in its fight on human existence; infant mortality is also succumbing. Man seems to be getting the best of the microbe.

As these diseases and their death rates go down, others rise to take their places. Cancer, kidney diseases, heart trouble, and other organic affections seem to be on the increase. The secret in combating these maladies in every case is early diagnosis. For that matter, diagnosis at the very onset is important in checking any disease and applies with special emphasis to many of those we have previously mentioned, such as tuberculosis. The average span of life in this country is increasing, but it would forge ahead much faster if the present knowledge regarding the communicable diseases were universally applied. It will increase even more when the rules of personal hygiene are thoroughly employed. Many more years will be added to this life span when new methods to cope effectively with the organic diseases are devised or discovered. In the meantime, health examinations have a real place in the advancement of our national vitality.

The growth of the health examination movement during the past decade has resulted in the production of some valuable data on the subject. Since there is no really succinct but adequate summary of all of these statistics, it is the purpose of this article briefly to review them. No claim is made for any originality of compilation or presentation of this material, but since the subject is likely to be more or less before public health workers during the next year, due to the propaganda of the National Health Council, it seems worth while to present some of the facts which have been gathered, and which in many instances are of considerable significance. Naturally, a great deal must be omitted. Extensive studies of industrial workers have been carried on and many examinations of infants and school children are on record. Since we are interested primarily in general health examinations for all ages, types, and classes of people, an endeavor will be made to confine this review to that class of data. It will be taken up in chronological order.

Growth of the Movement

Long before health examinations were even thought of, medical inspections of school children were instituted in 1892 as a routine procedure. At first only contagious diseases were looked for, but in 1895 more general examinations were given. Life insurance companies have examined prospective risks for many years and recruits for the army and navy have been looked over as a regular procedure for a long period. The first attempt to offer periodic physical examinations to the general public on a large scale, however, seems to have been that of the Life Extension Institute, which was established in January, 1914. To date (1923) more than 250,000 persons have received medical examinations through the institute. While this is the most extensive group of health examinations extant, tabulated figures of the results of the entire group do not appear to be available. The medical director of the institute, Dr. E. L. Fisk, is authority for the statement, though, that most of the persons examined are found to have physical impairments. Usually, the individual is ignorant of these defects and in a majority of instances they could have been prevented. Of course not all of these defects are disabling, but most of them may retard the efficiency of the individual to some degree and keep him below par.

In examining ten thousand workmen in one hundred industrial plants, the institute found none who were physically perfect (Class 1); 10 per cent had slight impairments (Class 2); 41 per cent had moderate defects requiring advice or minor treatment (Class 3); 35 per cent had moderate defects requiring medical supervision (Class 4); 9 per cent had advanced physical impairments requiring systematic treatment (Class 5); and, finally, 5 per cent needed immediate medical attention (Class 6). Similar results were obtained by the United States Public Health Service in examining nearly a thousand post-office employees by arrangement with the director of welfare of the Post Office Department in 1921. Of 985 who were examined and graded as above, only 5 per 1,000 went in Class 1, 12 per 1,000 in Class 2, 262 per 1,000 in Class 3, 341 per 1,000 in Class 4, 238 per 1,000 in Class 5, and 142 per 1,000 in Class 6. The Life Extension Institute had previously examined one hundred postal employees in New York City at the request of Dr. L. K. Frankel when he was director of welfare of the Post Office Department and obtained results almost exactly the same. All of these figures indicate the serious amount of disabilities and impairments among average groups of industrial workers.

The physical findings of the army draft during the world war have been rather thoroughly discussed, quite copiously alluded to, and often referred to as "the horrible example." The army draft was, however, the only real national physical examination which this country has ever had. About four million male persons between the ages of eighteen and forty-two were examined. The resulting figures of defects serve as an index to the condition of the whole country, bearing in mind that they apply only to men in the prime of life. Of 3,764,000 in the first and second draft, 555,000 were rejected as entirely unfit for service. Of about two million seven hundred thousands called to service, 47 per cent had physical impairments, a figure which Dr. E. L. Fisk believes is much too low. More than 11 per cent of those rejected had heart trouble and about 9 per cent had tuberculosis. The rejection rate for the first draft was 33 per cent and for the whole number in all drafts is estimated by the Surgeon General to have been 28 per cent. In Great Britain of 2,425,184 men who were examined in 1917 and 1918, only 36 per cent were graded as physically fit, 22 to 23 per cent.—(Continued on page 648.)

The One Best Way for Executives*

Self Command Means Automatic Response. Skill Means Repetitive Effort Reduced to Automaticity. Both Are Explainable in Terms of Habit Formation and May Be Readily Acquired

Dr. FRANK B. GILBRETH, CONSULTING ENGINEER, MONTCLAIR, N. J.

YOUR preliminary studies in the principles of administration are now completed. You have been studying the best theory and practice in your line of activity and are now ready to return to industry to apply what you have learned. You will find that the average practice of executives is far below the best that is already known and proved. Your practice as executives is expected to excel the best extant.

You are expected to give the world the benefit of the great opportunity that you have had. You are expected to function as the liaison officers between the most advanced school of economics, and the financial, commercial, and industrial world. You must be the makers and bearers of standards. Standards of thought and methods of analyzing facts and conditions for best results.

Having had exceptional privileges and opportunities, you are expected—you are duty bound—as a matter of patriotism, religion, and social service to spread the knowledge and methods of *measuring for action*, that their benefits may reach and help, to the largest extent possible, everyone with whom you come in contact and everyone whose destinies you can in any way affect or control. You are entitled to personal prosperity only in accordance with the extra prosperity that you are able to produce for your fellow men, and your durable satisfactions of life will be accumulated and enjoyed by you accordingly.

You are expected to help teach the differences between evidence and testimony as to the proofs of the "One Best Way" to do work, in order that actual measurements of the facts and actions of the past and present may be the prerequisites for judging trends and reactions and probable happenings of the future.

Your respect for the general practice of selecting the best units to measure, the best methods of measuring the units, and the use of devices that will make the most

prompt presentation of the facts, will create a new mental attitude toward and a more ready acceptance of the scientific method in commerce and industry.

You will live to see a revolution in the methods of executives. No such changes have ever been made in several generations as you will see in your generation. You will be called to guide the trend of the science of management and the happiness and prosperity of all classes from the educated to the ignorant, the skilled to the unskilled, the genius to the moron.

While you will find in many instances a marvelous application of genius to industry, close examination will everywhere reveal surprising inequalities of merit and efficiency. You will find as a direct result of such unevenness the most pathetic or ridiculous situations, for almost everywhere there is to be seen a careful and painstaking effort to perpetuate the practices and conditions that have long been acknowledged as obsolete.

For there are relatively very few who realize that high wages and low unit costs can be obtained simultaneously if employers and employees cooperate heartily in the time and energy saving methods standardized in the "One Best Way" to do work, and of this few there are still fewer who combine with this knowledge the continuity of purpose which is necessary to achieve this mutually desired result.

Old Notions Persist

Trades can be taught in one-fifth to one-tenth of the time that is now generally required, but nevertheless, you will find that even now trade schools are proposing further prolongation of the periods of apprenticeship.

This will obtain as long as training is permitted to remain in the hands of journeymen. Without the slightest knowledge of motion study, with no use of scientific method either in practice of the trade or in apprenticeship training, and with the further disqualification that they have almost every personal incentive *not* to produce skilled apprentices who through youth

and greater strenuousness will surely supplant the older man unless by mutual agreement all limit their possible output, it is natural that no records can be shown of trades holding before ambitious youths the methods which in their periods of leisure or during times of unavoidable inactivity they may employ to further their skill and shorten their periods of apprenticeship. The consultant of the apprenticed youth and the last word of authority for him is the biased and ignorant journeyman to whom he has been assigned as pupil.

No two workers and no two teachers of workers in offices or factory, on the farm or in the school, do their work in the same way. Study will reveal quicker, more economical, better methods in the best representative of each group. In each respective group, therefore, all may be counted wrong but one.

You will find that only a very small percentage of people realize the astounding economic waste resulting from the lack of a national and international effort to find and reward the representative of each group who can demonstrate the one best way to do work and all of the components that go to make up this one best way to accomplish a given result in trade or office work. The fact that relative skill in all kinds of repetitive endeavor can be so reduced is the basis for establishing the *best extant* for use as a base line from which to adapt and improve for better adaptation to the different types of individuals and the other conditioning factors that affect the quality of a man's work, the great idea being that such basic standard of possible achievement enables the worker to study his own work and to eliminate motions that are useless and hence entail an unnecessary waste of time and effort and produce needless fatigue.

Many of the current methods for doing work are shockingly, unnecessarily bad, and this condition is not confined to the practices of the uneducated laboring class. Crude methods obtain in all trades and vocations. Even in the hospital operating room

*An address given at the graduation exercises at the Babson Institute, Wellesley Hills, Mass., June 18, 1923.

and in the practice of surgery, which of all vocations should be regarded as precision activities, so much waste motion occurs that almost any thoughtful person should be able to improve them materially. The same is more particularly true in large mercantile establishments, and in the great retail stores.

No two surgeons are equally direct and precise, no two use the same methods. Among the great department store executives there is disagreement on fundamentals in different stores. Even executives in the same concern will find themselves opposing one another both in principles and practice on matters that are the proper subjects of demonstration rather than argument. The general use of charts for the graphic presentation of facts and the indication of probable trends is appreciated in the offices of but a small percentage of American executives, though they are at present more appreciated here than in any other country.

Many great executives who are otherwise justly famous, are opposed to the use of charts. Some refuse to look at them as though it were a matter of creed or religion, and many who do use them know but vaguely what they mean.

You will find that of those executives who are enthusiastic for the use of charts, not more than a trivial percentage realize the importance of the prophecy and program lines of the chart as outlining objectives and graphically setting forth a plan to be understood and to be provided for, and serving as a basis of comparison with the performance that follows. It is essential that the prophecy and program curves shall not be limited merely to financial analyses and budgets, but that the same methods be applied also to marketing, sales, and production, all of which must be considered together, as well as separately.

You will find executives who will approve of extravagant expenses on many kinds of non-essentials, and at the same time will watch carefully the amount of paper used in the making of the charts, and insist that the data be so crowded, that paper is saved at the expense of information that is to be presented to the under-executives. Business and industry and the country at large will be forever indebted to Babson for the emphasis that he has placed on the value and use of charts for presenting correlations, conditions, trends, and prophecies.

These facts will call to your atten-

tion a few typical instances of the extraordinary conditions and opportunities that will confront you executives when you return to your chosen fields in merchandizing, industry, and in the professions. You know that the remedies for such conditions exist and that it is your duty to apply them.

I have purposely emphasized the foregoing facts, not because I am pessimistic, but to impress upon you the absolute necessity of using for improvement the best demonstrator of the best method obtainable as a definite first step in the process for finding the "One Best Way" for executives.

Shocking degrees of unnecessary wastes exist on all sides. Such books as Professor Spooner's "Wealth from Waste," a remarkable thought detonator, give detailed accounts of such wastes and information regarding their elimination. One should also keep in touch with the work of waste elimination of the Federated American Engineering Societies, under the eminent leadership of L. W. Wallace.

You will find that a large proportion of executives, whose functions would seem to indicate that they know better than almost all of the rest of the people, have but slight concern regarding waste elimination except in materials. They will, perhaps, all agree that the waste from the kitchen should be fed to the hens, but there are still many who know nothing of the dependent sequence of savings accruing from the elimination of excess variety and size in manufactured goods. They know nothing of the theory of preferred sizes for full lines with minimum inventory, and they will persist in the fallacy that standardization of variety, size, condition, and method, is the cause of monotony, and the feeling that any office or factory operating under superstandardized conditions for intensive output would be a sort of a part-time jail.

You will find that many of our best magazines are ever ready to open their columns to writers who are without actual personal experience, who will describe the monotony that accompanies working under standardized conditions, a monotony which, as a matter of fact, affects only a worker who is capable of handling a grade of work above the type at which he is working.

You are supposed to disseminate information to counteract such illogical influences and conditions. You are supposed to know that there are all types of bodies and minds, and that there are many people who prefer to fill the jobs ordinarily considered to

be monotonous, and comparatively few who desire to take the responsibility that accompanies the jobs that require planning before performance or new decisions constantly during performance.

Instead of stressing the monotony of the worker who has no particular preference as to the kind of work, there should be much more emphasis on the subject of having each and every person occupy the highest position that he is able to occupy, and all that goes with scientific preparation, fitting and placement. *There is no problem of monotony when one works at the highest type of work for which he is fitted.*

You will find it the exception instead of the rule to paint all work rooms as white as possible. You will find a general belief that light reflected from white paint is too strong for the eyes, yet it can never equal the brightness of outdoors.

Executives everywhere generalize and decide with too little data on the subject under consideration, and the percentage of organizations that have mnemonically classified their information and data, and have filed them so that they are instantly available, is very small.

You will find many concerns, who, with the honesty of ignorance, will agree upon time study rates which they "will never cut unless the method is changed," and who will then entirely omit the recording of the method which is timed. You will find that the general practice is to guess instead of to measure.

You will find a pathetic condition regarding theories and practices of promotion to higher positions in the industries. You will find that relative merit and efficiency are seldom properly evaluated, due to the absence of individual records of performance. You will find better individual records of daily efficiency of cows on a dairy farm than you will find of workers in many organizations too large for the personal touch. You will find comparatively few instances where the individual's progress and promotion are planned, and where the skill of the expert is in transferable form for the use of the faithful and the ambitious. You will find few instances where the efficient can be sure that their utmost efforts will be recognized.

There are few organizations where teaching and fitting ones fellows is made an incentive resulting in benefit to all, yet this is comparatively easy of accomplishment. This is no mere theory. The three-position plan of promotion has been in operation

Editorials

THE first problem of the health officer is to develop a sound plan of progressive development in the light of local conditions and local needs. His second problem is to obtain the funds

necessary for putting such a plan into execution; and at this point the problems of personality again prove of supreme importance.

To Secure Health Appropriations

Experience shows that the popular support necessary for securing adequate health appropriations is latent in every community and that where the situation is properly presented it is a rare politician who can not be made to appreciate that the support of sound public health work is the best sort of practical politics. Yet appropriations in most communities are still woefully inadequate.¹ The health officer has something which every community needs, the possibility of saving life and promoting health through the application of the modern science of hygiene and sanitation; but he must be an effective salesman as well as a sound administrator if he is to persuade the city fathers to purchase what he has to sell.

The health officer who appears before his budget committee must first of all have his facts in order. He must know just what has been spent and how, and why, and he must know the exact purpose of every dollar of new money which is asked for. He must answer all questions frankly and fully and in such fashion as to convince the appropriating authorities that he is businesslike and economical. He must present the results attained and above all the possible achievements of the future in a form so clear and effective as to make it obvious that it is not some remote piece of scientific work which is at stake but the saving of lives of men, women and children. He must not seem to dictate and he must not seem to be asking for something for himself and his staff. Dictation and personal appeal alike produce psychological reactions which only serve to draw the purse-strings tighter. The most successful health officer at a budget hearing is the man who presents his case so convincingly and yet so objectively that when he has finished the appropriating authorities feel that he has laid before them an opportunity and not asked them for a subsidy.

¹ See article by H. H. Moore, Public Economy and Public Health, The Nation's Health, v. 343.

THE movement now on foot for the organization of a national society to sponsor the campaign against heart disease testifies to the progress of one of the most significant of the newer currents in the stream of public health. The Association for the Prevention and Relief of Heart Disease of New York City, established in 1915, has performed

Campaign vs. Heart Disease

a truly notable service. Forty-three out-patient cardiac clinics are now in operation in New York City with a registered attendance of about six thousand patients. Seven to eight hundred affected children have been cared for this summer in fresh air homes and three hundreds beds in various institutions have been made available for convalescent cardiac cases in need of institutional care. Sixty-one out-patient clinics for cardiac cases are now in operation in twenty-three other cities; but it is more than time that this admirable work should be extended with greater rapidity and made more truly national in scope.

To the layman there is something final about the verdict "heart disease"; as there was about the word "tuberculosis" fifty years ago. Yet in a very large proportion of cases such a feeling is altogether unwarranted. There are three broadly distinguished types of heart lesions, as pointed out in recent enlightening addresses by Dr. Lewis A. Conner, which coincides with three different age periods of life. In childhood heart disease is generally due to focal infections of various types, frequently associated with rheumatic symptoms; in middle life it is typically a sequel to syphilis; in later years it is most often a symptom of those degenerative changes which old age brings about in the arterio-renal complex.

The control of true degenerative cardiac disease is still limited chiefly to palliative measures and must so remain until a deeper knowledge of biochemistry reveals something more of the true nature of senile degeneration. The heart disease of middle life is however clearly within our power although the attack must be made primarily upon syphilis itself, at a time long antecedent to the actual incidence of cardiac symptoms. Every step which is taken to further the early diagnosis and the prompt treatment of syphilis will contribute just so much to the reduction of heart disease in the forties and fifties.

It is above all, the cardiac disease of children which offers a supreme opportunity for intelligent and organized control. If the focus of infection can be discovered and removed, by attention to teeth or tonsils for example, the secondary lesions

which have been produced will not only cease to progress but will tend to disappear. Like every other organ of the body, the heart is subject to the sway of the *vis medicatrix naturae*. It is here that results of major importance may be achieved and the development of social machinery adapted to this end offers substantial opportunities to the health worker of tomorrow.

THE many-sided social-hygiene program is being rapidly integrated into the general social welfare scheme of the United States as was well illustrated by the program of the National Conference of Social Work in Washington, last spring. The conferees—both those who prepared papers and those who discussed them—showed their complete

Tendencies in Social Hygiene

sympathy with the proposition that education for normal family life is an essential foundation stone for our whole social structure. Conversely they indicated a well founded understanding of the dangers arising out of familial maladjustments, so many of which are due to a failure of the marital partners adequately to solve their sex problems.

Less emphasis in the conference program was placed on the field of venereal disease control, mainly because this activity, to a large extent, has now attained its logical place in the work of national, state, and local official health agencies. The stressing of other phases of social hygiene was in itself a tribute to the progress already made in fighting syphilis and gonorrhea. It indicated a realization of the noteworthy advance made during the past ten years in the medical—and, to a lesser degree, social treatment of these diseases. The increase of from two hundred to 850 in public clinics throughout the country, and the fact that in addition to the Division of Venereal Diseases of the U. S. Public Health Service, virtually every state has an official bureau or division to combat these plagues within its own boundaries, are matters of almost common knowledge.

The increase in free laboratory facilities for carrying out the tests so essential as aids in scientific diagnosis and treatment, and the increase in the reporting by physicians of cases of syphilis and gonorrhea are also great. It is interesting to note in this connection that recent monthly letters sent out by Dr. Joseph Lawrence, director, Division of Venereal Diseases, New York State Department of Health, show more cases of syphilis being reported than of tuberculosis.

That the medical profession has gone farther with its portion of the social-hygiene problem than have the church, the school, and the home was shown by accounts of the lack of technique, training, and purposeful effort in the personnel of these three latter groups. It is to them, largely, that the future looks for preventive—rather than remedial, social hygiene.

The salvaging processes now being carried on in reformatories, industrial homes, hospitals, and clinics, will be necessary, probably, for many years to come, but constructive sex instruction should reduce this necessity, steadily and surely. When our clergy, teachers, and parents learn to evaluate in true terms the importance of accurate, wholesome, sympathetic counsel to youth from child- to manhood, they will so apply their knowledge as to lessen greatly the burdens of persons and institutions now dealing with the varied manifestations of sex delinquency.

VOLUMETRICALLY speaking, industrial medicine has made a remarkable record during the last decade. The establishment of new medical departments and the expansion of old

Opportunity of Industrial Physician

ones in industrial organizations has been a continuous performance. Qualitatively there have also been advances. But the excellence of industrial medical work has

not kept pace with the increase in its volume.

Not that industrial medical work is not good, has not grown better, or is not getting better all the time. It is. And many men of fine abilities are giving to it the best that is in them. It has also produced some studies and investigations properly classed as scientific research. Yet in too many instances it has concerned itself with the day's work only and there has been piled on the doctor such a burden of routine that he has had no time or energy left to carry his observations beyond the patient in hand.

The particular weakness arising out of this condition is in the field of industrial hygiene. Patients are well treated. Conditions and processes are often neglected. Preventive medicine is not studied at its sources. Light, air, and epidemiology are too often unknown quantities to industrial physicians. Safety departments have gone ahead of medical departments in this regard. They have applied the analytical method to the study of accidents and have gradually eliminated hazards that are not apparent on the face of things.

The industrial physician needs to learn that he is a hygienist as well as a surgeon. It would be more accurate to say that he must become a hygienist as well as a surgeon, for with only rare exceptions his training and interests are confined to the latter field. But in order to do this he needs more than the conviction that the field of hygiene belongs to him, is relatively untitled in American industry, and will yield a good return for the labor spent on it. Like our best physicians he needs better training in hygiene, beginning with the medical school. And he must have the support of industrial management, financially and in other ways, for the collection and analysis of data and for the application of the treatment he finds to be needed.

The general debility of the industrial hygiene movement will not be cured without the prolonged administration of this two-ingredient stimulant.

THE past two years have been banner years in the history of public health and have resulted in enormous strides in health education as well as in health preservation. Never before has

Golden Rule in Health Work

the positive health idea occupied such a prominent position in the minds of the mass of the people. In order to retain this interest and confidence, it behooves

health workers everywhere to exert their best efforts in the promotion of health and happiness, remembering that much depends upon their own enthusiasm and thoughtfulness.

In this connection it seems pertinent to sound a note of caution against the tendency on the part of a few health workers, particularly some of those engaged in routine clinic activities, to forget that they are dealing with human beings, possessed of sensitive psychological constitutions. During the emergency of war there may have been some reason for uncompromising orders or even occasional harsh words, but such exhibitions have no place in the properly functioning public health campaign. Routine clinic work is of course trying on the patience of the personnel in charge, but it is important to bear in mind that the value of the clinic as a public health educational center may be largely lost by neglecting the elementary virtues of tact and consideration.

A little girl came to a dental clinic a few days ago in company with a group of other children from her room at school. An older girl in charge of the group observed that the child was unusually nervous over the situation and suggested to the

dentist that she be examined first. But instead, the child was pushed aside until the very last to punish her for attempting to interfere with clinic routine; and in the end a slightly decayed tooth was hastily extracted without a pretense of examination to ascertain if it might have been saved. The child had come to the clinic with the usual permission from her parents for such treatment as she needed for the father and mother had confidence in the school authorities.

In place of establishing a health consciousness in the minds of children who will in turn pass on the message to the family at home, such treatment as that described above naturally embitters the children and parents and all with whom they come in contact, and a golden opportunity is lost simply through the neglect of an unsympathetic practitioner. Cases similar to this occur only too frequently in practice. It is very difficult in routine clinic, hospital, or sanatorium practice to smile continually in the presence of frequent annoyance. It is, however, worth while to remember that a kindly and patient attitude toward the patient will pay big dividends in health promotion.

TWO contributions of very real significance have recently been made to our knowledge of the reaction of the human body to atmospheric temperature and humidity.

Temperature and Humidity

On this side of the water, Houghten and Yagloglou¹ conducted a careful study of the effect of various combinations of atmospheric temperature and humidity on comfort and on the physiological reactions of the body, at the Research Laboratory of the United States Bureau of Mines, the United States Public Health Service, and the American Society of Heating and Ventilating Engineers at Pittsburgh. The results obtained seems to clear up a much disputed question as to the relative significance of wet and dry bulb temperature in determining comfort and show that at 32 degrees F., the comfort line coincides with the dry bulb temperature, at 62 degrees. It depends equally on the wet and dry bulb temperatures and at about 132 degrees the wet bulb temperature is the determining factor. As demonstrated by the New York State Commission on Ventilation and other workers body temperature and pulse rate are markedly affected by increasing air temperature.

In another communication from the same laboratory, McConnell and Houghten² report in

greater detail on the effects of more extreme atmospheric conditions, treatment being prolonged until the subjects were so markedly affected as to make a longer stay in the experimental chamber dangerous. Restlessness, irritability, headache, and palpitation of the heart, soreness of the eyes, weight on the chest, dizziness, confusion were the chief symptoms; and weakness and a dragged out feeling continued for some time after the experiment had closed. The extreme dry bulb temperature which could be endured was 157 degrees (wet bulb temperature 100 degrees, relative humidity 15 per cent) for forty-five minutes, while the extreme wet bulb temperature was 112½ degrees (100 per cent relative humidity) for thirty-five minutes. The pulse rate seemed to be the best measure of discomfort, 135 beats per minute being markedly uncomfortable and conditions becoming almost unbearable when the pulse exceeded 150 beats. Blood pressure results were somewhat variable but under the most extreme conditions the diastolic pressure fell and the systolic pressure rose. No changes in respiratory rate were observed.

From England we have a somewhat similar study by Vernon³ which indicates similar results so far as body temperature and pulse are concerned but which coincides with the work of the New York State Commission on Ventilation in indicating a somewhat delayed rise in rate of respiration. The particularly significant feature in these studies is the demonstration that under moderate degrees of overheating there is a tendency to reach a condition of equilibrium which the author attributes to the increased evaporation from the wet clothing. Particularly important is the demonstration of the importance of acclimatization, the endurable limit of wet bulb temperature being increased from 82½ degrees F. wet bulb to 88½ degrees F. wet bulb in the period of a month during which the experiments were conducted. Acclimatization was most effective in relation to humidity and manifested itself in greater power of endurance in a lessened increase in pulse rate and a lessened increase in respiration. Dr. Vernon believes that a specific influence is exerted by humidity per se irrespective of wet bulb temperature though in this respect his studies are perhaps less exhaustive than those of Houghten and Yagloglou. As might be expected he shows that the kata-thermometer is not a very close index of comfort when clothing is worn.

KANSAS CITY'S WEST SIDE DAY NURSERY

Welfare work for the child under five is quite as often welfare work for the mother as well. Tucked in between two tall buildings in a downtown district of Kansas City, the sand pile of the West Side Day Nursery gives the children of working mothers a chance to play freely and develop naturally in an atmosphere impossible in a city street or in a home where the mother is absent at her day's work. The gymnasium of the Downtown Branch of the First Baptist church serves the children as a play room. Ten cents a day pays for a day's care for two warm meals. Thus the nursery safeguards the critical pre-school period of the child's life.

The Fourth Man

BY WILLIAM COLBY RUCKER, WASHINGTON.

IT WAS a gorgeous day. The woods were marching beneath the flaming banners of autumn and little tufts of fleecy clouds moved slowly in a sky which seemed to sparkle with the first crispness of September. The course was crowded. Many players were waiting to take their markers out of the rack and drive down the velvety fairway which fell from the tee in a succession of green terraces broken by a wicked bunker and sand-trap maliciously placed to ensnare the unwary.

One foursome drew aside from the crowd and stood leaning on their drivers waiting their turn, their caddies sprawling near the tee with the sacks of clubs.

"Too bad about Exton," said one, a short beetle-browed man of judicial mien.

"How's that, Judge," asked another with saintly face and silver hair.

"Lost his wife, Bishop."

"Dear, dear—dear, dear—how sad. She was a lovely girl—so sweet—from such a good family—and he such a jolly fellow—such a brilliant lawyer and so popular. Dear, dear—dear, dear," clucked the Bishop.

"Died in the hospital this morning. Operation, I believe—poor Exton. Have know him well ever since he was admitted to practice—too bad. Such a generous chap—great mixer. A bit wild perhaps, very public spirited though. Always in everything—good speaker—banquets and all that sort of thing. Awfully sorry for him. Hard luck coming right now just as we were expecting to run him for Congress," and the Judge sighed.

"I knew him awfully well," said a big blond giant of a man. "We were in college together, same fraternity in fact, and while he was a little apt to stray off the straight and narrow, he had a heart of gold and a brilliant mind. Too generous a man though, always gave away everything he had. This surely will be a terrible blow to him."

"Yes—yes," said the Bishop. "It seems to me, I heard something about

him being in the hospital about a year ago. Not too strong himself, I fear, and now to lose that beautiful sweet wife, how sad—how sad," and the Bishop stepped back and made a practice stroke at an empty match box.

"Oh, well, I wouldn't worry too much about his health, Bishop," said the blond man with a wink. "Everybody—that is, um—all of us worldly men—have our little indiscretions, otherwise what would there be for you good men to do?"

"Indiscretions! Poor Exton! Poor

threw out the blond. "Mrs. Exton died in the hospital following an operation for some female complaint—"

"Sure she did," broke in the fourth man. "Where'd she get that female complaint? I'll tell you. From that high-roller, glad-handing husband of hers. That's where she got it. I know what he had when he was in the hospital a year ago. His wife thought he'd hurt his back in a motor-boat and when he didn't get well promptly, they told her he had some kidney

trouble. Kidney trouble, hell! He'd picked up something no decent man should have, knocking around with a bunch of half-soused lodge brothers. Of course he took it home. Of course he infected his wife and he killed her just as surely as if he'd fed her arsenic or bashed in her head with an axe. Murder, that's what it is!"

"Oh my—oh my!" and the Bishop twisted his driver nervously.

"But my dear fellow," said the Judge tensely. "It was not intentional. There was no premeditation. No motive could be shown. We all know his great affection for his wife and—"

"Affection, hell!" snorted the fourth man. "If that's affection give me hate. Affection, huh! Any man who associates even once in a while with a lot of common trollops is a potential

murderer. Perhaps it's his wife he's going to kill—perhaps it's his children—perhaps it's himself—it doesn't matter which—but potentially he's going to kill somebody. When an intelligent, educated man deliberately, drunk or sober, goes down the line, he knows—or at least he should know—that he's starting out to kill somebody. That's premeditation, to take life, and if his wife or child dies as the result, it's murder just—"

"But my dear man, you don't understand the legal questions involved," interrupted the Judge. "Granted the premise, it couldn't be anything more than an accident—criminal negligence if you will—hardly manslaughter, certainly not murder. You see—"

Healthologues in Fiction

THE parable has long been recognized as a valuable educational method.

It not only attracts the mind, it is a subtle means of making a lasting mental impression.

Many a good lesson has been taught by fiction that never could have been inculcated by tracts, and much health propaganda has been thrown away unread by laymen who would read with avidity a fiction in which the same facts are skillfully concealed. This will be the case so long as it is necessary to sugar-coat pills. The story herewith is an excellent example of the virtues of slantwise suggestion instead of a frontal attack.

hell!" burst out the fourth man. "I've had my eye on that brilliant mixer and semi-rounder ever since he went to preparatory school with my boy. I've always liked him—couldn't help it—he had a wonderful charm—and I admit his intellectuality and ability and all of that. But he had a bad streak. No, I don't mean just that. I mean a weak streak—vanity perhaps—the vanity that comes from good looks and charm and brilliancy and doing easily what others have to sweat blood over. But damn him, if he was my son-in-law, I'd kill him for a common murderer!"

"Oh dear—oh dear—how dreadful!" groaned the Bishop.

"What do you mean murderer?"

"See, hell Judge! The woman's dead isn't she? See, huh! When every school and college in the country is teaching all about these things, do you suppose anybody but a congenital idiot doesn't know what he's going up against when he picks up some cabaret huzzy? If I went out in my automobile and drove on the wrong side of the road and killed somebody you'd send me up for manslaughter wouldn't you? Do you mean to tell me that a man who puts himself in the way of getting a dangerous disease and then gives it to his wife doesn't deserve hanging? You give me a pain! Exton was a good looking and a free spender and full of fun, but he was a rotter and you're making excuses for his conduct. Do you know why? Because every darn one of us—except you Bishop of course—has been down the same road some time in our lives and we're afraid to look our souls in the eye and admit how criminally we've acted at some time or other and how dreadful the consequences might have been. Maybe there have been consequences but we've managed to keep 'em secret."

"Dear—dear," exclaimed the Bishop in a voice of pain. "That can't be true. You're all communicants. You've reared your families well. You're model husbands and fathers. It can't be true that even in the irresponsible days of your youth you've done such things. I can't believe it. I won't believe it!" Pathetically his eyes questioned each of them.

The blond man blushed and stirred the turf with his cleated shoe. The Judge cleared his throat. The fourth man looked at the other three defiantly.

"Well—er—you see," mumbled the blond man. "Youth—um—artificial restrictions of society—physical urge—um—little wild oats necessary—um, um—"

"Need we enter upon these irrelevancies?" pompously began the Judge.

"Oh, come clean fellows—come clean," thrust in the fourth man. "Let's get our souls laundered right here and now. We aren't sitting in judgment to one another. We aren't bragging about our youthful foibles. We aren't telling the world. We're a bunch of middle-aged, fairly successful, reasonably decent men. Nature left all that foolishness behind us long ago. We started by pitying a fellow who has lost his wife and we've gotten to the point where we're trying to fix the responsibility for her death. I say her husband killed her. The judge says it isn't murder but is almost willing to admit manslaughter

through criminal negligence but—"

"Just a minute please," cut in the Bishop crisply. All his hesitancy had gone. His dear old face shone like an angel's, a kindly angel talking to wayward children.

"Tell me gentlemen—as your spiritual leader, I have a right to know—I must know. Did you do what the fourth man implied you did? Did you ever go to these horrible places? Did you ever consort with these—ah—unfortunate women? Tell me."

The blond man's red turned brick. The fourth man grinned maliciously.

"Tell me," urged the Bishop.

The Judge swung a chalky face on the fourth man. "Damn your meddling tongue. I wouldn't have had this happen for the world. I'll never be at peace again!"

The Bishop laid a gentle, blue-veined hand on his shoulder. "Confession is the road to peace, my son. Tell me," he begged.

With a jerk, the blond man brought up his big blue eyes brimming with unheeded tears. "I did," said he, "twice—and I can't tell you how frightened I was afterwards. The last time was just before we knew our little boy was coming and I nearly died for fear he would be blind. The months of tormenting suspense cured me. He died when he was six. I've always blamed myself but our doctor said that never had nothing to do with it." He choked.

"I've strayed too," said the fourth man grimly, "and it wasn't until my boy went away to school that it came home to me. Thought the wife wasn't wise to me—fancied myself rather clever. Just before Dick left, she looked me straight in the eye. 'Do you think he's going to be as big a fool about women as you are?' she said levelly. I caved right in and I've kept straight ever since and thank God, my boy's as clean as a hound's tooth."

The Bishop's hand still rested on the Judge's shoulder. He shook it off as though it burned him and turned his ashy face upon the others. "I've lost my wife," said he.

The fourth man gazed thoughtfully down the fairway broken by a wicked bunker and sandtrap maliciously placed to ensnare the unwary. "It's not so hard, if you keep straight down the course," he said to himself.

The United Hospital Fund of New York City announces that it costs the city \$54,000,000 a year to be sick, and that 180,000 persons on an average are on the sick list each day.

Protective Value of Coloring Poisonous Drugs

The General Medical Council (England) has been invited to express an opinion on the suggestion that strychnin in future should contain "brilliant green" to an extent that would render it readily recognizable, and the further proposition that distinctive coloring matter should be added to such commercial products as sheep-dip and weed-killers, with the same object of preventing danger to human life through negligence or criminal intent. Commenting on the subject, *Public Health* gives the following expression from the Council:

It would, no doubt, be desirable in the interest of the patient or dispenser that drugs dangerous to life in excessive quantities, and used in compounding medicines, should be so distinguished that accidental failure to recognize them would become impossible. Such accidents are, however, not common, and a patient might be alarmed at the appearance of a medicine containing a perfectly proper ingredient. In the case of sheep-dips, weed-killers, poisons for vermin, and other substances in common use, criminal trials have shown that poisons such as arsenic can be used with fatal effect, and that their detection may only take place with difficulty when the death of a person poisoned has for some reason excited suspicion. Such suspicion, however, may not arise until it is too late to obtain proof as to how the poison came to be taken, and the form under which it was obtained. How many cases may escape detection altogether is not known. A very vivid and distinctive coloring might deter a poisoner or warn his victim, if it were undisguisable even in minute quantities and highly diluted. It would also, of course, assist in the detection of the cause of death. Whether it would tend to advertise the poison and its efficacy to persons desirous of using it for the purpose of suicide, or to would-be poisoners, who might trust to being able to disguise it, is a question which no doubt will receive consideration."

Pennsylvania Outlay for Relief Measures

The funds devoted in Pennsylvania to measures of relief are made up of: State expense \$24,914,897; county funds, \$12,503,297; and private charity, \$9,552,663. This money is spent as follows: 3.1 per cent for the prevention of tuberculosis; 15 per cent on work for children; 18 per cent for the care of acute illnesses; 26.3 per cent for outdoor relief and workmen's compensation; 39.6 per cent for insane, feeble-minded, almshouses, jails, penitentiaries, and homes for the aged; and .1 of 1 per cent for activities of the Department of Public Welfare.

Salt Lake City's New Municipal Bath House

CHAMBERS of Commerce all over America are more and more taking an active part in public health. This happy condition has been brought about by leaders in the public health field, who have demonstrated to the Chamber of Commerce secretary that the health of a community and the healthfulness of the community's surroundings are the best assets any town can have.

A public health program, perhaps more than any other civic activity, must adapt itself strictly to the community's needs and conform to the requirements of tomorrow.

Within the past few months Salt Lake City has just completed its new municipal bath house at a cost of \$350,000 and the Chamber of Commerce of Salt Lake City takes a great pride in broadcasting the information about these municipal baths, not only because of the fact that they are among the finest and most modern in the country, but also because this community asset has always been owned by the people of the city and the new facilities are utilized to better advantage.

The new bath house is 109 feet deep and 212 feet wide. It faces west, overlooking Great Salt Lake and commands a view of the various islands there in the lake and the mountains beyond.

The largest pool is fifty feet by 120 feet, finished in white tile throughout and this, with the eight private pools of various sizes can accommodate two thousand bathers at the same time.

The architecture of the building is Spanish Renaissance. It has beautifully shaped windows and the finish is a rich cream with red terra cotta trimmings.

The early history of Warm Springs, as the springs are called, is found in an old L. D. S. Church encyclopedia which says:

Of the variety of warm springs in Utah, the most noted and best known are the Warm Springs within the corporate limits of Salt Lake City. The

waters are limpid and smell strongly of sulphurated hydrogen and are charged with gas as combined with a mineral basis and as absorbed by the waters themselves. Dr. Gale is authority for the assertion that it is a harrowgate water abounding in sulphur. Three fluid ounces of water on evaporation to entire dryness in a platina capsule will give eight and one-fourth grains of solid saline matter. It is slightly charged with hydro-sulphuric acid gas and is a pleasant saline mineral water, having the valuable properties belonging to saline sulphur springs. It issues from the mountain side in large volume at a

the property. Under his supervision a flourishing business was done at the springs during the following ten years. In 1876 the property was leased to Dr. Monroe, who, however, failed to comply with his contract with the city council, in consequence of which James Townsend became the lease holder and had charge until his death, April 2, 1866.

The new bath house was constructed under the supervision of the City Commission, with Commissioner Herman H. Green, head of the Department of Public Affairs and Finance in direct charge. The bathing and other facilities, are described as follows:

One large pool 50 feet by 120 feet—for the use of the general public.

One medium pool, called the Private Pool, size 20 feet by 50 feet—to be used for private parties or otherwise as the management deems proper.

Seven small pools, size of each 8 feet by 11 feet, these to be for individual use.

There are twenty-six shower baths scattered throughout the building; thirteen of these are in connection with the large pool, four for the medium pool, seven for the individual pools (one to each pool), one

for the masseur's room and one for the masseuse's room. These are mainly for use in cooling off after a bath in the pool; most of them are supplied with cold fresh water only, although at least one shower in every shower room will be supplied with both hot and cold water.

Adjoining the main pool on the main floor at the south end is a large locker and dressing room for men, fitted up with dressing booths and lockers; in the basement directly below is a room of the same size for boys, similarly equipped; and on the second floor directly above, is a third similar room for women equipped with individual dressing booths.

These locker and dressing rooms are directly accessible to the main pool. Being on the south end of the building, they are also adja-

The bath house has a frontage of 212 feet, facing west, and overlooking Great Salt Lake. The building is of Spanish Renaissance in style, and is finished in a rich cream with terra cotta trimmings.

point about one quarter of a mile north of the Warm Springs Bath House.

It has a temperature of 95 to 104 degrees and is conveyed in wooden pipes into three bathing houses containing plunges, shower, and tub baths and dressing and waiting rooms. The water is very efficacious in the cure of many diseases, notably paralytic rheumatism and scrofula. The bathhouses are situated in the Nineteenth Ward on South West Street between Eighth and Ninth North Streets. The property is owned by the city with which it is connected by street cars. The Warm Springs bath house was first opened November 27th, 1850, on the block lying immediately south of the present bath house. It was under the care of James Hendrix. Subsequently J. C. Little opened a hotel on the premises and did considerable business. In 1866 the present bath house was built under the direction of the Great Salt Lake City Council and Henry Arnold was appointed superintendent of

The large pool, for the use of the general public, is fifty feet wide by 120 feet long. Twenty-six shower baths are distributed throughout the building, thirteen of them in connection with the large pool.

cent to the outdoor pool and are intended likewise to serve those who frequent that pool; side entrances have been provided for such purposes.

Adjoining the medium or so called private pools are two other larger locker and dressing rooms—one on the main floor for men and the other above, for women. Steam rooms are also provided adjacent to the showers and pools.

On the main floor close to the men's large locker and dressing rooms, quarters are provided for a barber shop and masseur with Turkish baths and special physical exercise room in connection. On the floor above convenient to the ladies' locker and dressing room are located a beauty parlor and quarters for a masseuse.

The bathhouse is heated by steam from its own plant located in a boiler room to the rear. The plant includes three steam boilers, any two of which are of capacity to take care of the most extreme needs; the extra boiler will be in reserve for any emergency or for winter weather. It will probably be necessary to operate only one boiler.

Two exhaust fans are required for ventilation of the inner rooms adjoining the pools; but the pool rooms themselves are ventilated through roof ventilators which will take away the excessive vapor constantly arising from the water.

On the interior, tile is used quite extensively—this material being sanitary, beautiful, and capable of resisting the action of the water; all shower rooms, steam rooms, pool promenades and walls of the pools themselves are white tile. Ornamen-

tal, richly colored plans received in the prize contest for tile with a small amount of marble is used also for the floors and trim in the main entrance vestibule and lobby.

The opportunities afforded by this new bathhouse are exceptionally good and every day a great many children and grown-ups frequent the invigorating waters of the new municipal bath house and while the building and

American Hospital Association in Annual Conference

The discussions which take place during the conference of the American Hospital Association have long formed one of our best indices of hos-

One of the small private bathing pools in Salt Lake City's bath house which is available for private parties or otherwise as the management deems proper.

pital trends. The fact that 129 persons are on the tentative program, each representing some vital interest and some pressing hospital problem to be brought up before various sections during the twenty-fifth annual meeting to be held in the Municipal auditorium, Milwaukee, October 29 to November 3, is evidence enough of the importance of the hospital of the present day as a social phenomenon.

The hospital plant will be demonstrated by an exhibit of plans of six hundred or more architects' designs, collected to facilitate study and comparison by the Hospital Library and Service Bureau. The fifty-one accepted

plans received in the prize contest for the best fifty-bed hospital will be exhibited by The Modern Hospital Publishing Company. The Wisconsin Tuberculosis Association will present selected types of sanatoriums.

The industrial exhibit will include a model hospital diet kitchen. Every detail has been worked out by expert committees so as to demonstrate the possibilities of maximum efficiency and service. Educational exhibits center chiefly around occupational therapy, while various committees and societies will demonstrate the social services of the hospital, and its responsibility in dispensary and out-patient service.

The scientific program is arranged for the convenience and interest of specialized workers into the following sections: (1) Hospital construction; (2) out-patient section; (3) administration section; (4) dietetics; (5) trustee section; (6) administration; (7) nursing; (8) social service; (9) small hospitals; and (10) general sessions to cover such topics as are common problems to all hospital people.

Spirochete Infection of Rabbits

Though the literature on spontaneous rabbit spirochetosis is not yet extensive a recent contribution by Warthin, Buffington, and Wanstrom (*J. Infec. Dis.*, May 1923, 32, 5, p. 315) support the authors contention that "it is disconcerting to find that there is a spirochete infection of rabbits, apparently widespread throughout the world, caused by a spirochete that resembles pallida sufficiently closely to make possible the occurrence of mistaken identifications of one for the other, in the case of any worker who is not acquainted with the two organisms and their differential diagnosis. It is unfortunately true that the great mass of experimental work on the transmission of human syphilis to the rabbit has been carried out in ignorance of the spontaneous rabbit disease, and the value of that work now becomes legitimately doubtful."

Veneral Disease Information

The publication of venereal disease information by the U. S. Public Health Service for the benefit of health officers, physicians, nurses, and social workers engaged in venereal disease control activities, heretofore sent out as a mimeographed report, will henceforth be issued in printed pamphlet form. Under topical heads of special articles, research, diagnosis, treatment, clinical notes, and administrative notes, all current information on the subject is covered.

Monitor Ventilation for Two-Story Buildings Used in Massachusetts

No Attempt Is Made to Harness Air in the Canton Hospital School, But It Is Allowed to Rise, As It Is Inclined to Do

VENTILATION by a rather unusual method is employed in the Building of the Massachusetts Hospital School for Crippled Children. This institution, under the direction of Dr. F. E. Fish, is located at Canton, Mass.

Monitor ventilation is not unusual in one-story buildings but the Hospital School is probably the first instance in which it has been applied to buildings of two stories. As designed by Samuel W. Mead, architect, the structure is essentially one single story building placed above another. The roof of the monitor on the first story is extended in a horizontal plane to cover the area of the first floor; on this the second story is erected. Advocates of this type of construction and those that have inspected the Hospital School speak highly of the results accomplished.

The following account of the history of construction at the school and description of the present system of ventilating the two story building by monitors in the ceilings of the lower as well as upper story rooms, is supplied by Mr. Mead.

The Massachusetts Hospital School was created by legislative act in 1904 and the Trustees proceeded to plan an institution for the care and education of three hundred children and so create citizens to be self-supporting who otherwise might have become dependents. Suitable food and housing was the first requisite for such a program and the trustees determined that the housing must be planned in one-story buildings which could be ventilated with a monitor in the roof. The Hospital School was something new, there was no such institution in existence for observation and comparison, so the whole plant was a new creation. Two buildings for housing were planned, one story buildings of course, each containing two dormitories and two class rooms. The dormitories were real barracks, 24x62 feet with a sloping ceiling with low

hip roof and terminating in a monitor 10x50 feet for ventilation. The class rooms were 22x30 but architects and laws said they must be ventilated in the usual way by circulating pure warm air. So this rule was followed.

These buildings, when used, demonstrated that the air changes in the dormitories were ideal. The monitors at the ceiling let in fresh air and at the same time discharged the foul air noticeable at night in changing soiled beds, etc. The air in the dormitories was always fresh in contrast

fully considered and provided for.

In the new building I made the monitor roof of the east ward with an 18-inch eave and for the west ward I roofed the monitor with a flat roof which extended like a canopy over the whole area (20x30) of the ward. When these wards were occupied and used this west ward demonstrated itself more efficient in ventilation than other monitors, and the extreme overhang of roof was a suitable guard against conditions of storm. This west ward demonstrated

perfectly an ideal design for ceiling ventilation which could be duplicated in rooms placed one above another. Previous to the construction of this ward, monitor roof ventilation was unknown to buildings of more than a single story in height.

It has been found through experience at the Massachusetts Hospital School, in rooms constructed with sloping ceilings terminating in a monitor fitted with hinged windows, up or down air currents may be made and controlled.

In every case at this institution the heating is from direct steam radiation in the room. There are no air intakes. The fresh air comes in from open windows, leakage, or from the windward side of the monitor. The weather conditions govern entirely the ventilation and there is no rule of operation. Under no conditions of weather is it necessary to open the windows in the room, for ventilation can be controlled by operating the windows of the monitor.

Since the building of the original dormitories and the infirmary referred to, a cow barn, a two story cottage for boys, a two story cottage for girls and the New Bradford Infirmary, a handsome fireproof building, two stories high, accommodating one hundred bed patients, have been added to the plant.

All of these buildings are planned

Exterior view of part of the Massachusetts Hospital School, Canton, Mass., showing between the first and second stories the openings which connect with the monitors in the ceilings of the first floor rooms.

with the air in the class rooms which appeared fairly "dead." The class rooms had flat ceilings, and heat and vent ducts as required by the Massachusetts laws.

Ceiling Ventilation Perfect

The following year new buildings were planned, this time a small infirmary was necessary, and a building with two small wards was planned. These wards were planned 20x30 feet and followed closely the original dormitory model with sloping ceilings following a low hip roof and terminating in a monitor 9x18 with small windows opening out.

The only change of these monitors over the original dormitory monitors was to improve the eaves of the small monitor roof. Originally they were scant, the ventilation was right but protection against storm had not been

with monitor roof ventilation throughout, in large units and small units, to suit the housing, and in every case the ventilation is most acceptable.

The sloping ceilings start seven to eight feet above the floor line and

Monitor ventilation in a corridor of the Massachusetts Hospital School at Canton.

slope from the four walls to fit the roof line. The new Bradford Infirmary which has just been occupied, and found to be sufficiently deserving to bear the name of Dr. Edward H. Bradford, will prove to be the best development of monitor roof ventilation to be seen.

The first story of this building has a clear height of 13 feet. The ceiling slope starts 7½ feet from the floor and terminates at the monitor 10 feet from the floor. The second story clear height from the second floor to monitor ceiling equals the ridge height of the main roof of the building or 19 feet. In this story the ceiling slope starts 8 feet above the floor and terminates at the monitor 16 feet above the floor. The monitors are standardized to a 4-foot width for either story and the windows are all one light of glass 30 inches wide and 10 inches high, hinged at the bottom and swinging out.

It will be seen that these monitors are less than half the width of any of the earlier buildings, the windows are also only half as high, and these changes have proved that the air currents are more easily controlled; although the first story is 6 feet lower than the second story, the ventilation appears to be as efficient.

This novel idea of creating one story buildings in vertical association and so gain ceiling ventilation over and over again has been received by

professional men with a good deal of skepticism as to the architectural effect of the exterior, but I think the Bradford Infirmary has demonstrated that a fine looking building can be created under these conditions of design. Another building in Canton, Mass., with monitor roof ventilation is the Revere School a one story building of four school rooms planned in the form of a Greek Cross and monitors are planned much the same as in the Hospital School buildings.

There are several modern schools in Canton, but the Revere School is the latest building, so is the only one with a monitor roof. After some hearings at the State House on the subject of ventilation a state commission visited the schools at Canton to make comparative tests, with the result that the Revere School tested out as far superior to the others in every condition. In my practice of architecture I have been commissioned to plan many schools and churches in and about Boston all of which were necessarily designed with the common standards of ventilation operated by mechanical means, but since my experience covering ten years of study and planning the monitor roof system for the buildings at the Massachusetts Hospital School, I am convinced that cities and towns are wasting millions and millions of money in attempting to do with apparatus what can be accomplished in nature's own way.

Is it not obvious that a ceiling sloping from four sides to a hole in the roof will release the circulated air better than a hole near the floor at one side of the room? If my contention is right then it is true that enormous sums are being wasted, not only on apparatus, but on building construction and maintenance costs for schools.

Question of Air Intake

I have no doubt but that my monitor roof ventilation contention will be accepted in part by architects and engineers, but the question of air intake seems to be questionable with them, for generally speaking, the practice of emptying heated air into a room has seemed to be the right solution of heating for comfort. This has been the custom in luxurious homes from choice, and in public buildings to conform to building laws. My experience makes me believe that mathematical heating and ventilation is leading us astray, the fact is we are still animals instinctively directed to make the best choice. We prefer spring water to rain water for drink-

ing and a whiff of good outside air is a relief after sitting in a school or hall for an hour or so. When heating engineers can be led to forget about forcing air and plan to let nature take its course in an upward circulating system then the senses of school children will brighten, the doctors will have less frequent calls and the janitor in the basement will be free from care and be able to concentrate on the care of the building. To illustrate all this I shall refer again to the Bradford Infirmary at the Massachusetts Hospital School, for it is the best heated and ventilated building I know. It is a thoroughly modern hospital for every requirement of medicine and surgery and provides for the classification of one hundred bed patients, in four wards of 12 beds each, four wards of six beds each and the rest in private rooms, a few of which take two beds, and the heating and ventilation of this entire building cost less than

View of the type of monitor used in ventilating ward at the Massachusetts Hospital School at Canton.

ten thousand dollars. We should not try to harness air but be satisfied with intimate association with what air wants to do.

Chlorosis, a type of anemia once very prevalent among young women, is reported in Guy's Hospital Reports as fast disappearing both in Europe and America. The matter is of much more than merely medical interest because its control is attributed to the greater amount of exercise and fresh air enjoyed by women of today than in the past. The marked change for the better in the general health of women is definitely coincident with the first insistent demands for outdoor life and regular exercise for girls.

School Bazaar Interests Parents in Child Health*

*Diets in the Past Have Stupidly Played Tricks With Nature, But Now
Both Parents and Children Are Better Informed*

MOST professional health workers, particularly those who specialize in school work, recognize that one of the greatest difficulties is not getting the ideas over to the child, but rather how to reach the parent. Granting that some will come to us, in most cases Mahomet has to go to the mountain. How to do this, or in fact how to interest parents in school health work in a fashion which will be conducive to results is one of the questions on which our plans largely depend. For this reason I am presenting a report of two health projects undertaken in the DeValles School (named for Father DeValles, a well-known hero of the recent war whose death resulted from injuries in the service).

Early in the year, a Home and School Association was formed, with regular meetings, and a live set of officers. They cooperated to the utmost and consistently followed the suggestions of Mr. Louis Cook, a principal who has done unusual health work and who has been getting re-
sults thereby.

The second meeting was a Health Meeting and was for parents only. The program consisted of several suitable reels of moving pictures obtained from the State Department of Hygiene interspersed with a short talk by the school nurse, stressing the teeth and their care and by an illustrated talk by the Director of Health and Hygiene entitled A Child's Day, the discussion including diet and health habits. The attendance was good and considerable interest was aroused.

For the May meeting a more ambitious project was decided upon and

with which this article will deal chiefly. A health bazaar was planned consisting of exhibits of interest to parents, plus a health play in which the children would take part.

Every possible source of material was considered in order to make the exhibits as diversified and as valuable as possible and special thanks are due to the Eye-sight Conservation Council of America, the National Committee for the Prevention of Blindness, the Massachusetts Society for Mental Hygiene, and the Massachusetts De-

partment available for further investigation. Such parents as were interested were referred to a nutrition booth which will be described later. As decorations for this particular section a series of health alphabet posters, made by the children were used and others depicted the value of milk.

Next were three booths for selling simple candies at moderate prices, as well as articles made by the children, and finally five and ten cent grab packages.

Next to the grabs, a nurse was in charge of a scale where all might be weighed and measured without charge and tables were available for determining whether or not the figures were normal.

The nutrition booth occupied the corner of the room and was in charge of the health instructor in nutrition from the state department of hygiene. Here several rows of seats were placed and she was able to discuss the subject briefly with small interested groups of about twelve or fifteen, besides giving individual advice to parents who had been referred to her by the

David (in bed) is served by Eddie Egg, Mr. Milk, the Milk Girls (glasses in hand), Bacon, Butter, and Bread. Other clues completed the health message, and song, dance, and dramatic interest drive the lesson home.

partment of Hygiene for loan material.

The entertainment took place in the school hall which will seat about a thousand. The doors entering this were decorated with posters on nutrition and immediately upon entry the visitors came upon a booth in charge of the school nurse and an assistant who were prepared to weigh and measure any given child and if the child belonged in the nutrition group, they were ready, with accurate and fresh information to explain what measures were probably needed to bring the pupil back to normal. The findings of the school physician were given to interested parents, the cumulative health records being instantly

school nurse or who were especially interested. The Metropolitan Life Insurance Company furnished a supply of their cook books, child health alphabets, and other literature of great attractiveness and practical value and this was distributed in the school department by the supervisor of nurses, who assisted the nutrition worker.

The baby clinic which is held weekly in this particular school by the Board of Health provided an exhibit consisting of scales, baskets for use as cradles, and other practical articles.

There was in addition the school dental hygienist with her complete outfit who demonstrated her methods

*We are indebted for this material to Hugh Grant Rowell, M.D., then director of health and hygiene in New Bedford, Mass., schools. Dr. Rowell is now lecturer in physical education and assistant physician to Teachers College, Columbia University.

of cleaning teeth, in spite of the fact she had already handled twenty children that day. Showing the parents how such things are actually done is very conducive to a reduction of difficulty in securing permission for giving the child something of the utmost benefit.

On the third side of the room was a poster exhibit of the Massachusetts Society for Mental Hygiene, consisting of a rather remarkable series depicting essentially faults which a parent should guard against in the growing child that the man may become a citizen in the true sense of the word.

Nearby was a group on Eyesight Conservation provided by the Eyesight Conservation Council and of considerable practical value.

In a prominent position was a unique series of Safety First photographs, enlarged to poster size and depicting the policeman as a friend of the school child as well as showing in a striking manner the possible accidents resulting from carelessness of a child as regards street cars, automobiles, explosives, all depicting either the actual person who received the injury, following the accident, or else certain posed photographs demonstrating the very happenings at the time of the disaster. This is a group gradually becoming somewhat famous through the efforts of Officer White, a policeman detailed as Safety First instructor in the schools and through whose efforts the child accident incidence has largely decreased. The idea is unique and Officer White is very much a pioneer in the field, very few cities having this feature at present.

Having seen the exhibits the audience were ready for the play. The popular approval of the whole plan was easily demonstrated by the crowd which overflowed the hall.

The play was called "David and the Health Elves" and was under the direction of Miss Talmage, a teacher of considerable experience in this work. About two hundred children took parts. The scene was a bedroom, painted in yellow, with the nursery idea carried out in a border of animals which formed the upper portion of the room. A window played a very

To take no interest in ablutions is as bad for the health as to take no interest in food. The baby clinic is responsible for teaching the girls of this school how to bathe the baby.

prominent part and was used to prove the value of fresh air. The children took parts as fairies and elves, with a number representing various vegetables. A number of group and solo dances were distributed through the entertainment. The costumes were well-conceived and exceedingly attractive.

A rough outline of the play is of interest. David is sent to bed, goes to sleep and dreams of elves appearing with messages of how to keep well. Each elf represents some health habit, some food, or some type of foods (protein, etc.). Sunshine and rest fairies come in review and sing David to a quiet sleep.

Miss May Bliss Dickinson, director and founder of the mothercraft courses in the New Bedford Schools.

Some of the important numbers were the "Keeping Clean Dance," the "Health Habit Drill," the Soap and Water Song, "House and Clothing Clean" by the elves and the "Dance of the Fresh Air Fairies." Exercise and song numbers introduced good things to eat, such as "Fruits and Vegetables" who give a dance and song; Captain Milk who leads all foods; "Song of the Milk Fairies," "Dance of all the Foods," "Sunshine and Sunbeams," "Rest Elves," "Song of the Rest Fairies." Each emphasized in a striking fashion certain points regarding

hygiene and health.

The children of the school learned more of health in a most attractive fashion and the thousand parents who crowded the hall received valuable instruction as well and enjoyment. Interest in health literature was marked and the literature was not thrown away.

A Health Bazaar of this type takes much time to prepare, but for real interest and reaching of the very hearts of both parent and child, is highly effective. Having aroused the interest we hold it by more stable and

less showy methods but having made the liaison between home and school as regards health work, results are forthcoming.

Newspaper publicity was gained at the same time. The *New Bedford Sunday Standard* gave a half page feature write-up with photographs and two other articles, each about one-third column in length; the *Morning Mercury* gave two similar stories about a third column each, and the *Evening Times* about the same. In addition several personals of those in charge were printed.

Women's Colleges Study Charity Work

A four weeks' intensive program covering such main fields of social work as medical social service, industrial personnel work, parole and probation, child welfare, immigration, and delinquency, was conducted by the Charity Organization Society of New York City during the month of July for the benefit of representatives from twelve eastern colleges chosen by Student Faculty Committees to utilize this means of securing a well-rounded impression of the requirements of the profession of social work. Observations made will be carried back for the benefit of the classes represented.

A fourth edition has just appeared of the "Handbook of Tuberculosis Schemes," published by the English National Association for the Prevention of Tuberculosis. It gives ready and trustworthy information regarding the operation of tuberculosis activities throughout Great Britain and Ireland.

Development of John B. Stetson Company's Welfare Activities

The Better the Workman, the Better the Work; Hence the Most Complete System Is the Most Profitable

THE welfare activities of the John B. Stetson Company are numerous and varied. Through a long period of years—from 1865, the year of the founding of the business—a system has been built up step by step which aims to make the life of the employee happier and more secure and to enable him to enjoy the full benefit of his work. "In much of this development the company has been a pioneer and has had to feel its way," says the pamphlet called "The Human Element in the Stetson Business." The company has spent and is still spending annually, great sums of money in its welfare work, but none of this is in any sense considered to be charity—either by the officials or the employees."

The company, acting on the principle that the better the workman the better the work, makes an investment in good-will, health, skill, and efficiency. The John B. Stetson Company has in operation several schemes in the nature of profit-sharing plans which are based on the merit system. "A careful record of each employee is kept through the year, and at Christmas time he is rewarded according to his effort." Cash benefits alone have in some years totaled as much as \$550,000.

Twenty-one thousand shares in the Building and Loan Associations have been issued with a total par value of \$4,200,000. The chief purpose of this association is to enable employees to secure their own homes and the only restriction on the allotted shares is that they may be borrowed on only for the purchase of real estate.

In 1897 only 35 per cent of the hat sizers had worked steadily throughout the year. A bonus plan was put in operation and since 1902, when the bonus was increased to 20 per cent, practically

100 per cent of the men have been working steadily.

Since 1902 more than six thousand shares of the company stock have been distributed among the employees making more than one fourth of them

rendered by the company. "There is no feature of its welfare work to which the company has devoted more thought than to the providing of working conditions that are perfectly sanitary. The Stetson Company is housed in splendid buildings of brick and steel construction, designed to allow the maximum of window space. One's first impressions on entering the factory are those of space, light, and air; of fresh paint and clean floors. All parts of the factory are painted at regular intervals by the company's own painters. The twenty-eight acres of floor space are scrubbed or otherwise cleaned once every week, most of this work being done by electric scrubbing machines. A vacuum cleaning system has been installed.

The sanitary system is on a par with the systems of most modern office buildings. Filtered and ice-cooled water is pumped through pipes that supply every department. Most of the dressing rooms are equipped with shower baths. And the toilets fitted with the most up-to-date fixtures are kept spotless and odorless.

Two rest rooms and a first-aid room are located near the women's working quarters. In the first aid room a graduate nurse and assistant are in constant attendance. The factory physician is on duty every afternoon at 3:30 to go over all cases that need redressings, and then at 4:30 has office hours in the building when employees may consult him about their condition, if they need medical service. The first aid room treats from one thousand to twelve hundred cases monthly. A dentist gives as much time as is needed to care for the teeth of the employees.

The more serious cases coming to the first aid room are treated by the

Welfare visitor and company nurse in front of the Stetson Hospital.

stockholders.

To encourage saving, a Christmas Club was started. Some then found that they had saved more than they cared to use for this purpose and, the company agreeing to pay 5 per cent interest on sums not withdrawn founded a Saving Fund, the deposits soon reached a total of \$160,000. A cooperative store is also in operation selling groceries and non-perishable foodstuffs. Members may also buy their coal at a saving through the

The cafeteria kitchen of the Stetson Company is typical of the high grade of sanitary installation maintained throughout.

store and arrange for payment on a weekly basis.

The financial provisions, however, are not the most important services

physician or sent to the Stetson Hospital, nearby. This institution while having provisions for sixty or seventy people is not restricted in its use to the company employees who constitute only 13 per cent of all patients. The hospital is thoroughly modern in every respect and maintains a large out-patient department.

Applicants for employment are required to undergo a thorough physical examination. If any employee fails to report for two days a visiting nurse calls at the home.

The company maintains four cafeterias, smoking rooms, an auditorium for the use of the employees, athletic field, classes in Americanization, a Sunday school with an average attendance of more than nine hundred, a Boy Scout Troop, Field Corps for older boys and girls, a chorus and other organizations for the activities of the young people of the neighborhood.

A Factory Management Committee, provisions for the adjustments of complaints and grievances, suggestion system, executives club, quarter century club, pensions for long and faithful service, sick benefits and group insurance, are other factors that add to the welfare and content of the workers.

A recent communication from Milton D. Gerhis, Second Vice-President says, "We feel, however, that the light and airy condition of our rooms, the filtered water supplied in every department, possibly has more to do with the health of our people," than any other of the activities.

Finger Printing as a Means of Identification

The value of infallible means of identification is the basis of a resolution asking that the New York Law (Chapter 466, Sec. 1237-9) "be so amended as to include foot printing of all children at birth, to include the finger print of the mother of said child, which must appear on the birth certificate; the finger printing of both parties to a marriage license and the finger prints of all deceased on all death certificates, and that all children be fingerprinted at school age."

It is said that a measure of this kind would greatly simplify the tasks of identifying abandoned babies who remain unidentified, of locating lost children, victims of aphasia and amnesia, and of finding the relatives of stolen children, or of those who meet accidental injury.

The procedure is advocated by the International Association for Identification and the New York measures have the support of the 350,000 women represented in the New York Federation of Women's Clubs.

Important Changes in Pennsylvania Hospital Law

The Pennsylvania legislature has passed and the Governor has signed an amendment to the county hospital law, which gives counties the right of eminent domain in acquiring land for tuberculosis hospital purposes and also gives the hospital board and the county controller joint supervision with the county commissioners in erecting such hospitals. As amended Section 2 of the county hospital law now reads as follows:

Section 2.—If a majority of the voters upon such question at such election shall be in favor of the establishment of the hospital the county commissioners, county controller, where such office exists, and board of trustees, hereafter provided for, shall have plans and specifications prepared and shall select and acquire a site for such hospital by purchase or condemnation with the same power and with the like procedure as land is now acquired under existing laws by school districts for school purposes, the county commissioners exercising the authority exercised by school directors for that purpose. Such plans and specifications and the location of such site shall be approved by the Commissioner of Health before the construction of any building is commenced. Upon the approval by the Commissioner of Health of the plans and specifications and the location of such hospital the hospital shall be constructed and equipped under the direction and supervision of the board of trustees, the county commissioners, and the county controller, where such office exists, and in the same manner as other county buildings are constructed and equipped.

Under this change it is expected that several counties which have not made progress in providing a tuberculosis hospital will be able to act soon.

Employees' Mutual Benefit Associations

Under the above title, Bloomfield and Bloomfield of Boston, consultants in industrial relations, have published privately a survey of the organization and methods of administration of benefit associations. It contains tabulations of the company, plan, and date established; eligibility require-

ments; methods of administration; source of funds; benefits; and methods of amendment and dissolution for twenty associations and administered by the employees, eighteen administered by both company and employees, and five administered by the company.

Such plans date back to about the year 1870. The employee-administered association usually has at its head a governing board, the company administered plan is headed either by the personnel director with necessary assistants or by a special committee, while among those jointly administered the widest variations are found. In a large number of the latter type a certain number of the governing board are appointed by the company and a certain number elected by the employees.

Poison Gases Utilized to Fight Mosquitoes

Poison gases, such as used in the World War, will be employed to fight the mosquito, according to an announcement recently made by Frederick A. Riley, chief inspector of the Mosquito Extermination Commission of Atlantic City. The day is about over, he said, when a mosquito can menace the lives of thousands. The New Jersey agricultural extermination station has been experimenting with different chemicals and gases. Drainage of the salt marshes is only a temporary measure, and most of the methods of treating the water protect against the breeding places for short periods of time only, but it is hoped by means of poison gases to destroy the danger centers permanently.

Beginning June 15 the welfare department of the Yellow Cab Company, Chicago, has maintained an infant welfare station at the Keystone Hospital for the benefit of the children of employees.

Minnesota Recommendations on Health

The committee on public health of the League of Minnesota Municipalities, received full support of the League in their recent convention in their program looking toward the promotion of uniform municipal health laws throughout the state. They went on record as opposed to the fee basis of financing local health departments, and as in favor of state aid to every school district proportionate to the number of children, for the purpose of holding annual or semi-annual medical examination of all school children, and for the employment of nurses.

The City Manager and Public Health

Frederic J. Haskin, in a news service article tells the following story of Petersburg, Va., showing how the adoption of the city manager plan of government effected public health.

In 1920 there were 1,600 houses in the city without water or sewer connections. Now, after an expenditure of nearly \$400,000, the work of extending the water and sewer system is nearly complete. Only 300 houses remain without connections and nearly all of these will be reached in 1923.

Under the old government the garbage was collected by the city engineer under the supervision of the street committee. The incinerator was conducted by the health officer under the supervision of the health committee. The two committees did not agree, so the garbage was hauled to a dump, where it caught fire from time to time and made a frightful nuisance, and the incinerator worked only a few hours a week to burn what was hauled to it from private stores. The streets were extraordinarily clean in some sections where "white wings" swept them several times a day—in the neighborhoods of wealth—and just as dirty downtown and in the other sections.

Now all the garbage from all the town is burned in the incinerator, and the streets are swept in all parts of the city. The whole street cleaning and garbage collection service has been reorganized. Approximately twice as much work is done as under the old system. The cost is about \$10,000 a year less than it was.

Having laid the foundations by these fundamental sanitary measures, Mr. Louis Brownlow, the city manager, addressed himself to the improvement of the public health service. He took the health department from three little rooms upstairs in an old building and put it in a building of its own, called the health center.

There, under one roof, are centered the health activities of the community, public and private. The venereal disease clinic formerly conducted by the Red Cross was taken over by the city, and the Red Cross opened in the health center a child welfare station and baby clinic. A tuberculosis clinic was opened, after a survey of the entire city and the actual clinical examination of more than 1,700 persons has demonstrated the need for the service. The bacteriological laboratory not only does the contagious dis-

ease work and the water and milk control work for the city, but also diagnostic laboratory service for private physicians for a fee, making the laboratory practically self-sustaining. The mothers clubs, the associated charities case conferences and many other organizations interested in health hold their meetings at the center.

The number of citizens coming to the health office for definite health

death rate for colored babies was 229. In 1921, it was 212. In 1922 it was only 128.

Services of the U. S. P. H. to Industry

The value of properly kept medical records does not end with the plant that keeps them. The U. S. Public

Health Service has for some time been collecting industrial statistics in order to obtain fundamental information needed for effective disease prevention work. As yet the Service is ignorant as to the actual prevalence of diseases that cause suffering and loss of efficiency but not death. Knowledge as to the sickness "expectancy" for all industrial employees and for certain kinds of employment is needed.

If enough sickness records can be obtained to permit generalization after making due allowance for fortuitous conditions and hazards the standards and averages establishes can be used by plants for comparison with their own sickness rates. Such comparison will probably indicate to many of them why some of their departments have found it difficult to keep men.

The Public Health Service will, whenever possible, be glad to cooperate in the study of sickness and disease prevention in different plants by helping them to devise forms that are especially suited to the plant and that yet conform to certain standard requirements, and by helping in any analysis of the records that may tend to improve working conditions and to lessen losses due to sickness.

The Service will be glad to receive from any plants regular reports that

conform to standard requirements, and to tabulate, analyze, and publish statistics based on them.

In certain instances the Service will assist companies in making a detailed analysis of their sickness records in order to measure the bearing of such factors as sex, age, nationality, marital status, occupation, and length of time employed, on the incidence and severity of disease.

A COSTARICAN COSTERMONGER

A Costarican market may be an open, unprotected plaza, it may be a stall contrived with a few palm leaves and old sacking, or it may be a cart like this trundled along the village street. It is not usually very stimulating to the appetite.

INSECT CONTROL IN PANAMA

Marketing breadstuffs in Panama is made safe so far as dust and insects are concerned by approved carts fully protected with glass covering.

service has been increased tenfold, in two years. The result is that both in 1921 and 1922 the city had the lowest morbidity rate and the lowest mortality rate in its history, lower in 1922 than in 1921.

Infant mortality shows a remarkable decrease. In 1920, the infant mortality rate, both white and colored, was 161. In 1921 it was reduced to 149. In 1922, with the health center fully organized, it was reduced to 106. The record among the colored population is astounding. In 1920 the

American Home Economics Association in Annual Meeting

THE economist of all persons achieves perspective. He discovers trends, and perceives that the minutest movement of his own becomes part and parcel of the world's work. He learns that isolation either of facts or acts is not merely stupid; it is impossible. It follows that when the economist elects to concern himself about the everyday affairs of life, order evolves and a more scientific accounting is made of every potential. There are many who see in the rapid growth and extending activities of the American Home Economics Association what may be considered as one of the best indications of sound social intelligence.

Untrained housewives are the rule, not the exception. Everywhere home-making, the finest of the fine arts, is learned in the painful and expensive school of experience. There is help for the situation, however, through the home-makers' committee of the American Association of Home Economics. For the first time time-study is being correlated on labor in the home. Leisure for the housewife is not only made desirable, but is being found possible to secure; and ways are devised to make it profitable to thousands of women formerly ground down by never-ending tasks. Actual supervision in the application of home budgets is conducted by the extension division. Whether the income applied to household needs is a thousand or a hundred thousand, wisdom in appropriation is acquired, not gained by a chance gift. Perhaps it is because many of the most difficult problems are encountered in incomes of large amounts that the graduate in home economics resents calling her service to the home-maker social service.

Whether the devotees of home economics choose to call themselves professional consultants or home missionaries, the results are enormously beneficial and their influence on the increase, for the Association has gained in membership from a meager eight hundred two years ago to 4,840 at the present time. Eleven hundred members, made up chiefly of the professional and business quota, registered at the sixteenth annual meeting held in Chicago July 30 to August 4.

Much interest was in evidence in

the sessions of the Homemakers' Committee. Studies of the housewife's working day (winter schedules), reported from the University of Missouri by Mrs. Elsie Park Duncan, show that an average of six hours and ten minutes must be devoted to daily household tasks, this representing one hour and thirty-seven minutes per person. Only efficient management can secure requisite leisure for the housewife. Time and energy saving devices contribute their part. Practicable time schedules must do the rest. The Iowa work day plan, definitely helpful and practically tested out, was discussed by Miss Anna E. Richardson, of the University of Iowa.

One section was devoted to the problems concerned with institutional management, a subject having as many phases as there are institutions. Its commercial aspect was treated by Vernon G. Stevens, of the La Salle Hotel, Chicago. He devoted much of his time to the fundamental requirements in economics for the training of successful hotel administrators. A course for hotel administrators as worked out by Cornell University is based on a four year high school curriculum requiring fifteen units—to include three in English, three in a foreign language, one in algebra, one in geometry, one in history and the remainder elective. To this is added eighteen units, apportioned among the fundamental sciences, bacteriology, physiology, physics, the science of nutrition, composition and character of foods, quantity cooking, and laboratory practice in cooking.

The responsibility of a hospital for the dietary supervision of students and house employees, professional and otherwise, was described by Rena Eckman, Michael Reese Hospital, Chicago. The high school and university were likewise considered, as were subjects having to do with the status of training in home economics for positions in the commercial field. Unusual interest and very wide business affiliations were manifested in the activities of the Home Economics in Business Committees. Both press and commerce were well represented. An urgent appeal was made for better rapport between academic and commercial forces by M. E. Harrison of

Washburn Crosby Company, Minneapolis. Anna E. Richardson of the Iowa State College discussed the business of buying. If, as one authority has stated, 85 per cent of the buying is done by the housewives of the country—practically all of them untrained for such function—it is time, said Miss Richardson, that some of the emphasis placed upon production be transferred to the business of buying. The University of Iowa maintains a group of 724 women in its extension division who serve in the capacity of budget advisories. Miss Richardson made a very rational argument for more intelligent and more accurate advertising. The annual expenditure in this country for advertising is around seven hundred million dollars against a sum of about fifty-five million dollars for education. A good product is, of course, wasted unless the consumer is advised of it, but honest advertising is imperative, and its educational aspect is not to be overlooked or underestimated. Business can and should have the objective of rendering the home mechanically efficient through educational advertising.

The days of business secrecy are over and the merchant now furnishes reliable information to the consumer.

The scientific program reported on experimental studies, and Dr. Arno B. Luckhardt reported on the physiology of hunger and appetite on the basis of researches being conducted by the department of physiology of the University of Chicago. Laboratory demonstrations on various subjects were open daily to members of the convention.

Officers were elected as follows: Alice F. Blood, Simmons Colleges, president; Frances Swain, Chicago Normal College, vice-president; Katherine Blunt, University of Chicago, vice-president; Anna Richardson, Iowa State Agricultural College, vice-president; Mary Sales, Ohio State University, secretary; H. G. Turpin, Baltimore Trust Company, Treasurer; Lita Bain, Grace Dodge Hotel, Washington, D. C., executive secretary; and Keturah Baldwin, 1211 Cathedral Street, Baltimore, Md., office secretary.

The 1924 meeting will be held in Buffalo, N. Y. and the conference will be held on the Pacific Coast in 1925.

Day Nurseries in Industries in France

About ten years ago the directors of the *Galeries Lafayette*, one of the big department stores in Paris, becoming justly alarmed at France's decreasing birth-rate, started a most interesting experiment. They determined to demonstrate that work for married women was not incompatible with motherhood. To this end they organized a day nursery for the babies of their 8,500 employees.

The day nursery is established on the premises in several adjoining clean and airy rooms, and is free to all infants of employees from one to fifteen months of age.

Each mother receives at the time of her confinement two months' leave of absence from work with full salary (fifteen days before the confinement and six weeks after), and she comes back to work bringing her baby with her. These mothers are entitled to arrive half-an-hour later and leave half-an-hour earlier than the other employees so that they escape the general rush.

The only condition of admission to the day nursery is that the mothers shall nurse their babies, if they are able to do so. In order to do this they are allowed to leave their work every three hours to feed their children. Before entering the feeding room, each mother puts on a white overall so that the child shall not come into contact with her working clothes. If the mother's milk is insufficient, the nursery provides extra milk, which it receives twice daily from the country around Paris. In addition, the business, while providing lunch for all its employees, allows each mother a supplementary milk ration.

Any child suspected of illness is immediately put into an isolation room, and, if proved to be unwell, is at once taken home by the mother. Thanks to these precautions no epidemic has ever broken out in the nursery, which

is regularly visited by the doctor in charge. Once a week all the babies are weighed and the result noted on the observation sheet which contains the life history of each little day-boarder.

tiny chairs, and the motherly pride of the matron in charge are all proof that the experiment made by the *Galeries Lafayette* has proved wonderfully successful.

The example has been followed by other big Paris shops, including the Louvre, which in some cases have also opened day nurseries and in others grant special maternity benefits to their employees.

Good Food and Scholarship Related

The Northwestern University girls recently nominated for Phi Beta Kappa are not so reserved and studious as they are at times pictured. One secret of their scholastic success is not in midnight oil, but in wholesome food and regularity in eating. At Willard hall, where several of the honor students reside, their bill of fare includes no such stimulating beverage as coffee or tea; the drinks are limited to cocoa and milk.

From a survey of the 150 women living at Willard Hall, Miss Bernice Gordon, house director, has just discovered that the scholarship girls are those who never fail to eat breakfast on schedule, and those who are lax in table attendance invariably rank low in class work. For breakfast Willard hall girls are served with food enough to satisfy the keenest appetite. Fresh fruit heads the menu each morning, followed by meats, or eggs, and warm breads.

Miss Gordon admits that much of her time is consumed in preparing charts of food values estimated in terms of calories and vitamins. The average college girl needs approximately two thousand five hundred calories per day. Of course, she says, some

who are athletically inclined need more and others can thrive on less.

Fresh vegetables have a prominent place on the tables at Willard. Head lettuce with thousand-island dressing is the favorite salad. Their favorite dessert is steamed chocolate pudding with hard sauce.

MATTHIAS NICOLL, JR.
New Commissioner of Health of New York State

MATTHIAS NICOLL, JR., who succeeds Dr. Biggs as Commissioner of Health of the State of New York, was born in New York City in 1868 and educated at Williams College, (A.B., 1889) and at the College of Physicians and Surgeons, New York (M.D., 1892). He specialized in pediatrics and the care of infectious diseases. His work, in co-operation with Dr. W. H. Park, on the intraspinal injection of tetanus antitoxin was of fundamental importance in demonstrating the superiority of this procedure as compared with other methods of injection. In 1915 Dr. Nicoll was appointed director of Public Health Education and Secretary of the recently organized State Department of Health of New York and since 1917 he has served as Deputy Commissioner. Dr. Nicoll is a fellow of the New York Academy of Medicine and of the American Public Health Association and a member of the Advisory Editorial Board of the *NATION'S HEALTH*.

The whole atmosphere of this delightful day nursery is one of health and happiness. The spotless cleanliness of the white cots with their gay blue coverlets, the fat cheeks of the babies who lie on their backs playing with suspended toys, toddle round the pens, or sit in solemn conclave in their

Coloring for Foodstuffs

THE maker of sweets only seventy years ago used as coloring lead chromite, Prussian blue, red lead, and vermilion, although even before the advent of coal-tar products he had at his disposal a number of harmless vegetable substances—such as litmus, indigo, and sap green from the berries of the buckthorn, cochineal, gamboge, turmeric, and saffron. Today, in the United States of America, and largely in England, the use of the following mineral pigments for food coloring is permissible—manganese brown, ultramarine blue, ultramarine violet, ultramarine green, and iron oxid brown. All that can be said against these colors is their insolubility, their complete indigestibility, and the fact that relatively large amounts must be used to give sufficient color.

A paper read by Mr. F. W. Richardson, F.I.C., public analyst for Bradford, West Riding, etc., before the Leeds Junior Branch of the Society of Dyers and Colorists, and abstracted in the *British Food Journal*, in discussing this subject goes on to say:

Aniseed balls contain as much as 2 per cent of iron oxid brown. It is an offense under the Food and Drugs Act to use more than half a per cent of French chalk or mineral silicate in the facing of rice. Why should it not be an offence to use excess of mineral colors in sweets? The danger of both kinds of substance is the same. By modern methods dyestuffs are made in a reasonably pure condition, and therefore the action of the colors themselves on the human organism need only be considered. With regard to the action of specific groups, nitro and nitroso groups are more or less toxic, whether they replace a hydrogen atom in the nucleus or one in a hydroxyl group.

Aurantia, the ammonium or sodium salt of hexanitro-diphenylamine, and picric acid are poisonous, while naphthol yellow S, known also as the sodium or potassium salt of dinitro-a-naphthol-b-monosulphonic acid is not poisonous, as in spite of two nitro groups the presence of a sulphonic acid group causes neutralization of drug action. Another harmless yellow is Curcumin S, also known as "Sun Yellow," the sodium salt of azoxy-stilbene-disulphonic acid. Naphthol Yellow S and Tartrazine are the chief yellow food colorings now used; sometimes under the significant name of

"Egg Yellow." Of late years there has been an undesirable increase in the number of so-called "Egg-substitutes," "Egg-powder," and the like, the only resemblance to eggs being the color. I think the Ministry of Health should take action. One of the most widely advertised of these specious articles consists entirely of rice flour colored with orange yellow dye. The analyst must see to it that by no chance Martius Yellow is used in place of the sulphonated derivative Naphthol Yellow S, as it is poisonous.

The following red dyes are safe to use because of their heavy content of sulphonic acid, and their freedom from nitro and nitroso groups—naphthol red S (amaranth, fast red D, bordeaux S), chloramin red B (benzo scarlet BC), carmoisin (azorubine S, fast red C), ponceau 2R, fast scarlet BC, and rhodamin B. Some beautiful colorings can be obtained by the use of eosin. Erythrosin D and B contains 40 per cent of its weight in iodine, and is yet safe for use as a food color, but the amount necessary to give a pink color is very small. Xylene blue BS and gentian blue 6B are salts of triphenyl rosanilin and triphenyl-para-rostanilin. This is said to be physiologically inert, as are blues derived from diphenylamine. A similar blue is nigrosin, but the fact that it is only soluble in spirit, and has a black tone, renders it unserviceable for food coloring. Methyl violet 6B usually contains over 20 per cent of zinc, as also does victoria green or new fast green 3B, but violets and greens, such as malachite greens, new victoria green, new green, fast green, ethyl green, emerald green, fast green J, and benzaldehyd green, are made without zinc, and are regarded as harmless for food coloring.

In the United States the use of diamond green and fast green is permitted, as also is dinitrosoresorcin. The only brown dye recommended by the U. S. A. authorities is chrysamin R, the sodium salt of di-tolyl-disazo-b-salicylic acid. Brown is, however, only used for sweets, and the color chosen is usually an iron oxid brown. The facts that malachite green and brilliant green are antiseptics of wide application, that methylene blue is useful internally for rheumatism, cystitis, nephritis, etc., and that scarlet red stimulates the growth of epithelium over granulating wounds, are scarcely good arguments for their admission into food.

Fat Consumption Figures in Different American Cities

Fats of various kinds to the amount of 4,600,000,000 pounds or an average of 43.8 pounds per person, are consumed annually by the people of the United States, says the *New York Times* on analyzing a study of this subject reported by Mr. F. M. Barnes, head of the Edible Oils and Fats Division of the Procter & Gamble Company. "If all the edible fats consumed yearly in the United States were laid end to end in pound prints," said Mr. Barnes, "a cable 353,280 miles long would be built. Such a rope of pure fat would wind fourteen times around the globe and have a little matter of 3,280 miles left to loop up in a bow. This impressive quantity however, is 1,385,000,000 pounds less than should be eaten, according to dietitians, who claim that at present the average per capita consumption is some thirteen pounds less than it should be and give fifty-seven pounds of fat per person per year as the correct individual quota for perfect health.

"Government figures show the growing inclination of housewives to turn away from lard to vegetable fats. Whereas twenty-five years ago lard was practically the only cooking fat used in the home, vegetable fats now make up 33.82 per cent of the whole amount used in American kitchens. The figures for fat consumption in various cities of the United States vary greatly, owing probably to differences in cooking habits based upon climate or foreign traditions, but they serve to show the trend of diet locally. According to the figures, gathered by local authorities, each of the 191,601 inhabitants of Omaha eat 153.9 pounds of fat a year, while the 993,739 people of Detroit eat only 37.8 pounds each. Little Rock's 65,142 inhabitants consume each 188 pounds, or a total of 12,260,620 pounds of fat per year. Birmingham, Ala., with 178,806 as the figure of population consumes 13,630,000 pounds, or 76.2 pounds per person. Atlanta, Ga., with 200,610 persons consumes 9,334,000 pounds, or only 46.5 pounds for each person. The people of Washington eat 48.6 pounds, of St. Louis 48.7, of Grand Rapids, 71.

A little booklet entitled "Open Doors" has been written by Dr. John Thomson for the mothers of mentally defective infants. The advice given is simple and practical. The book should be useful to child welfare workers, nurses, and even doctors as well as mothers.

Optimum Weight in Relation to Longevity

A distinction must be made between the optimum weight and the average weight says the *Statistical Bulletin* of the Metropolitan Life Insurance Company for March, 1923. In the past the average has often been assumed to be the best weight and tables of averages have been very widely circulated and used as guides by physicians, nutrition and clinic workers and others concerned with the health of children and adults. In this way there has sprung up the general assumption that deviation from the average weight was undesirable and indicated trouble.

We now know that such assumptions about the normality of the average weight are erroneous. In fact, it can be shown that the most favorable mortality experience is often found among risks whose weights are considerably below or above the averages for their height and age.

At ages under thirty years, the lowest mortality rates among insured persons are found in risks whose weights are above average. An excess of about ten pounds in weight above the average produces the most favorable mortality rates between the ages of twenty and twenty-four years. This excess tapers off until about age thirty, where the most favorable mortality is found among persons of approximately the average weight. After age thirty, the more favorable mortality rates are found among persons whose weights are below average. The amount below average increases with advancing age and at age fifty, individuals appear to be at their best when their weight is as much as thirty to forty pounds below the average.

It seems clear, therefore, that for persons beyond thirty, underweight is distinctly an advantage so far as a favorable prospect of mortality is concerned. It is erroneous to suppose that weight should increase with age, as we have been led to believe by the tables for average weights. This increase with advancing age is, of course, a very common occurrence, but there is every indication that it is a disadvantage and should be carefully avoided. The public health movement in its attack upon the diseases of

adult and later life will do well to bear this fact in mind.

Periodic Medical Examinations

In a paper on the periodic medical examinations of apparently healthy persons (*J. A. M. A., May 12, 1923*,

Open air exercise is absolutely necessary to health in the tropics, and golf courses may be found in many tropical places, and the game is entered into enthusiastically by foreigners and natives alike. The courses, like the Panama Golf Club, are adapted to local conditions and freckles and red-bug bites are regarded as trophies in the quest for health. There are three golf courses on the Isthmus of Panama, located at Panama, R. P., Fort Amador, C. Z., and Gatun, C. Z. Shorter courses are being played at Pedro Miguel, C. Z., and Fort Clayton, C. Z. They are crowded each day by enthusiastic men and women.

80, 19, p. 1376) Haven Emerson presents forms for recording the results of the physical examination as well as the history. The author discusses the purposes, methods of examination, and results, relating these to the forms presented.

Findings from the examination of 958 apparently well persons in New York City are presented. These individuals of various races, both sexes and all ages, chiefly among the wage earning class either considered themselves well at the time or were aware of some condition for which they did not consider medical care necessary. Of those examined 2.5 per cent were found to be in good health, 72.7 per cent needed definite medical treatment (this number included over two hundred who needed, in addition, advice as to personal hygiene and habits), and 24.7 per cent needed only hygienic advice to correct or arrest existing errors of bodily function or defects of structure.

Increase in Use of Pure Water in New York State

Eighty-six per cent of the people of New York state are now supplied with drinking water from public supplies and 73 per cent of the population are served by treated or purified

water, according to C. E. Holmquist, director of the Division of Sanitation of the State Department of Health, who has just completed a special investigation and report on the filtration and chlorination of the public water supplies of the State. Mr. Holmquist finds that 9,182-

000 persons in New York state out of a total estimated population of 10,651,000 are now supplied with water from public water supplies and that 7,796,000 persons are served with treated or purified water.

"In 1906, when the Division of Sanitary Engineering was organized and supervision over public water supplies was commenced, about 6,000,000 persons were served by public water supplies and only about 700,000 persons in the State were served by purified public water supplies. It will be seen therefore that since 1906 there has been an increase of some 53 per cent in the number served by public water supplies

and an increase of over 1,000 per cent in the number of persons served with water from purified supplies."

Investigation of Wages in the Candy Industry

There has just been issued by the Women's Bureau of the United States Department of Labor a report summarizing the results of an investigation made by the bureau of labor conditions in the candy industry as typified by candy factories in Chicago and St. Louis, the two cities studied.

One of the points particularly studied in the investigation, which took place during the early months of 1921, was the subject of wages received by women workers in the candy industry. It was found that the time workers constituted by far the largest proportion, 83.4 per cent of the women included in St. Louis and 69.8 per cent of those in Chicago. A comparison of the median earnings of the time workers and the piece workers in the two cities shows that in each case the piece workers earned in round numbers 17 per cent more than did the time workers, St. Louis showing \$11.45 per week for time workers and \$13.40 for the piece workers, and Chicago \$14.35 for the former and \$16.80 for the latter.

Controlling Malaria at Low Cost

"To determine whether a small city, a town, or a rural area could be protected against malaria at a cost which the local population could afford, the International Health Board," says President Vincent, "began in 1916, in cooperation with state and federal authorities, a series of demonstrations in small towns in Arkansas and Mississippi. The net result of these experiments was so encouraging, that for the season of 1920 widespread demonstrations were begun under the joint auspices of the local governments, state health departments, the United States Public Health Service, and the International Health Board. The program for 1922 included 34 county-wide malaria control demonstrations and 32 town demonstrations in ten states. All the demonstrations have afforded cumulative proof that under normal conditions an average community can practically rid itself of malaria at a per capita cost of from forty-five cents to one dollar per year. In addition, the Board conducted experiments in mosquito control by use of fish and by screening under a variety of conditions, and tested the curative and protective possibilities of quinin."

Shower Bath Standards Promote Hygiene

Of interest to those planning shower baths, either for public institutions or private use, are the suggestions of the Committee on Shower Bath Standards of the American Association for Promoting Hygiene and Public Baths submitted at the Annual Meeting of that Association, held in the City Hall, Jersey City, N. J., May 11 and 12.

The chairman of the committee is August P. Windolph, of Werner & Windolph, New York City, the other members being Robert F. G. Kelley, superintendent of the Baltimore Public Bath Commission, and Arthur M. Crane, General Manager of The New York Continental Jewell Filtration Co., Nutley, N. J.

The suggested standards were ordered broadcasted, with an invitation for criticism, in the hope that formal action can be taken at next year's Annual Meeting. The standards suggested are as follows:

- (1) The showers and dressing compartments should be well lighted.
- (2) The shower and dressing compartments should be constructed of a material impervious to water, sanitary and easily cleaned. The interior surfaces of compartments should pre-

sent a perfectly smooth surface with as few cracks and crevices as possible to avoid the shelter for dirt and disease germs.

(3) The floor of compartments should be of a sanitary material and sloped to carry off the water used in bath and should be non-slipping.

(4) There should be an ample supply of hot and cold water at all times.

(5) All pipes, fittings and valves should be of heavy and durable metal placed so as to be easily accessible.

(6) The shower head should be self-cleansing and so constructed that the water consumption may be controlled, and placed at the top of the shower compartments set at an angle of 45 degrees.

(7) The hot and cold water should be controlled either with a mixing valve so designed to prevent back water pressure or with separate valve on each hot and cold water line.

Aid in Food Rationing for the Family

The Nutrition Bureau of the New York Association for Improving the Condition of the Poor has issued in their publication No. 120 a book on "Food for the Family" which tells how to feed children of different ages properly; gives the proper diet for a nursing mother, and for the mother before the baby is born; plans menus that show how to prepare meals to fit the needs of both children and adults, and indicates how such meals may be arranged with economy in mind, or, how eggs, butter, milk, vegetables, and fruit may be added to advantage. Recipes are given for the different dishes, and a section on the lunchbox gives helpful bits about buying economically.

Diet in sickness likewise comes in for attention and directions are given for buying and marketing records which afford a check upon the adequacy of the dietary as well as upon costs. Get the housewife anxious to do all she can for her family, and give her this handbook, and intelligent and effective management will certainly improve the status of the family.

Medical Survey of Maryland State Prisons

Of interest to all officials of corrective institutions is the report of the committee of Baltimore physicians who last summer made a constructive survey of Maryland state prisons. Examination of the methods, equipment and evident needs of the institutions, and comparison of the data with re-

ports of conditions prevailing in the other states, comprised the agenda of the committee.

The general conclusion reached was unfavorable to the medical organization of the prisons; the service was pronounced grossly unsatisfactory and the equipment lamentably inadequate. In the way of improvement the committee recommended a complete reorganization, having for its general aim "social progress in preventive science, including on the one hand medical science whose diagnostic and therapeutic contribution rendered before it is too late tends to correct and restrain both mental and physical tendencies leading to delinquency; and on the other hand social science, which tends to raise standards of life among the masses and thus reconstitutes the mileau whence vice and misery spring." A study of the physique, intellect and character of each prisoner is advised; and an inquiry into the environmental factors that have impelled him or her to commit crime.

There should be a special officer known as medical supervisor, as well as the resident physicians; and two visiting consultants, specialists to be called when required, two trained nurses and two trained social service nurses.

It was estimated that the carrying out of the proposed plan would require \$11,800 per year, an increase of \$3,600 over the medical expenditure during the past fiscal year.

Japan Eumulates American Preventive Work

Dr. Rioji Tozawa, director of the Municipal Tuberculosis Sanatorium in Tokyo, Japan, who came to the United States for the purpose of attending the International Health Conference in San Francisco, states that methods of disease prevention, more particularly as carried out in child welfare work and tuberculosis work, are being intensively discussed in Japan. Dr. Tozawa is particularly desirous to duplicate in Japan the nutritional work he has observed in the United States, and to develop the possibilities he sees for public health cooperation between Japan and cities on the Pacific Coast.

During the first quarter of 1923 4,882 nurses have applied in California for renewal of their certificates as required by Section 5½ of the Registration Act. This registration will enable the Bureau of Registration of Nurses to compile the most complete list of nurses yet secured in California.

Craig Colony Care of Epileptics

Craig Colony, (Soneya, N. Y.) for Epileptics has issued its twenty-ninth annual report. Craig Colony differs from the average institution of the kind in that it does not confine its objectives to the custodial care of its population, but designs to accept only those epileptics whose condition may be improved under scientific and humane care. And the scientific and humane care are provided. The condition of patient life has been thoroughly protected, principally through the maintenance of social conditions adapted to their limitations; routine methods, and educational procedures—adequate, yet perfectly adapted to the needs of the handicapped group—have promoted happiness and have made effectual and productive living possible for the two thousand persons numbered among its population.

The need is great. Probably no single public health problem of the present day is more extensive or more universally pressing than the segregation and care of epileptics. Any community desiring to meet this problem can do no better than to study the ways and means evolved at Craig Colony. Here every possible means of ameliorating this dread condition are employed, and scientific observation on a large scale is continuously bringing out useful facts in regard to the disease. The report includes several interesting features of medical activities in the interest of the patients. Death usually results from some concurrent condition. The unusually low incidence of malignant disease is ascribed to the usually foreshortened span of life in the epileptic. Average readings of blood pressure gave no indications of a reciprocal relationship between hypertension and

epilepsy; in fact, if the records indicate any deviation from the normal in this regard, it tends to suggest hypotension. Lines of original investigations have been hampered chiefly by the lack of funds, but the chief work of the year was a study of hematology of epilepsy, including minute investigation of some three hundred patients, which seems to indicate a moderate but persistent increase in the number of leukocytes in the blood.

The daily number of patients cared

lack of facilities for the proper distribution of exhaust steam is responsible for an annual waste that is the actual equivalent of more than one thousand tons of coal.

Personal Factors in Accidents in Steel Industry

Machinery is no longer the main causative factor in accidents if the figures taken from an analysis made of more than 250,000 accidents occurring in the plants of the United States Steel Corporation and reported in the *New York Times* may be taken as representative of other industries. In this series hand labor was found responsible in 41.04 per cent of the accidents recorded and only 4.88 percent of the accidents could be traced directly to machinery causes, exclusive of accidents attributed to overhead cranes.

It becomes increasingly evident, says the report, that mere mechanical device for protection has a much smaller place in the safety program than consistent measures of education to reduce the hazard of the irresponsible workman. The United States Steel Corporation, therefore, systematically informs all operatives of the inherent dangers of given processes and, by giving special attention to the personnel factor, have been able to get the majority to accept the principle of interdependence of workmen for mutual safety.

Approximately nine thousand employees are members of safety committees whose function it is to make plant or departmental inspections, review accidents, and make suggestions regarding the problems of increasing the safety of operation. It is conceded that the industrial hygienist has a specific problem in this direction.

Gains in Child Labor Legislation

Gains in child labor legislation for 1923 show an improvement in child labor laws in only eight states. The legislatures of forty-four states have convened since the national child labor tax law was declared unconstitutional. Thirty-two of these states have laws which do not measure up to the standard of the federal law. In only eight of these—Delaware, Maine, Michigan, Missouri, North Dakota, Rhode Island, South Dakota, and Wyoming—was there any improvement in the age and hour standards. The failure of the states to deal severally with this urgent question is held by the Federal Children's Bureau to indicate that it is a national, not a local problem.

RIVERLIGHT, VACATION HOME FOR BLIND

Underwood & Underwood
Riverlight, probably the only vacation home of its kind in the country, is a vacation home for the blind conducted by the New York Association for the Blind. Located in an historic house in a seven-acre plot, the home has taken care of four groups of blind visitors throughout the summer season. Hiking, swimming, boating, calisthenic drill formed the summer's routine, the same as thousands of other camps throughout the country. The guests of the camp washed their own dishes and cared for their own beds and clothes.

for was 1,535, and the per capita cost for 1922 was \$360.90, a cost that is comparatively low because of a margin of profit on farm, garden, and dairy products in the amount of \$19,467.71—a very strong argument in favor of colonies for the feeble-minded. That economy of administration is hampered here, as is usual in most state institutions, by badly balanced appropriations is shown by the demand for service which greatly exceeds the limit of two thousand admissions, and by the lack of provision for certain limited numbers who require merely custodial care. A glaring lack of unintelligence in appropriation is brought out by the fact that ten years ago legislative appropriation permitted the erection of a smoke stack of sufficient capacity for an adequate central heating plant, but thus far the balance of the necessary funds for completing the plant has not been forthcoming. Meanwhile, as shown by the engineer's report, the

LATE HEALTH DECISIONS IN THE COURTS

By DOROTHY KETCHAM. UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

ON SEPTEMBER 14, 1916, an employee, sixteen years of age, while employed as a rivet heater by the Union Iron Works, fell from a ladder, breaking both his legs and an arm. It is conceded that the injury arose out of and in the course of employment. The company placed him under the care of two physicians, but later removed him to their own private hospital, where he was treated by petitioners own physicians. The injuries were severe and for four years after the injury there was a drainage of pus from one leg due to necrosis of the bone and unhealed wounds. During this time he went around on crutches, wholly unable to work. His treatment for the entire four years after leaving the hospital, consisted largely in calling daily at the hospital and having the dressing changed. He lost faith in the treatment when his condition was apparently growing worse and consulted a doctor who advised immediate operation to remove the diseased bone. He reported this to the petitioner's physicians, who felt that such an operation would not be opportune until the clearing up of a discharging sinus in the left leg, in which they were confirmed by the opinion of another physician and the medical director of the Industrial Accident Commission. After waiting a month for the petitioner's physicians to relieve his condition, the injured employee in November, 1920, abandoned their treatment and placed himself under the care of Dr. Hunken (previously consulted) who operated twice, the operations being a complete success. The discharge was stopped, the bones united, the wounds healed and the injured employee discarded his crutches and became self-supporting. The employee then made application for an award covering expenses of operation and treatment by Dr. Hunken. There is no question of malpractice, damages, or fault on the part of the employer. We cannot here go into the various considerations raised.

The action is founded upon the provisions of the Workmen's Compensation Act whose underlying principle

is "the providing of compensation to an employee for injuries resulting from his employment." It emanates from the economic thought that personal injury losses incident to an industry are a part of the cost of production, to be borne, just as the depreciation and replacement of a machine is borne, by the industry itself, which compensation will be included in the cost of the product of the industry.

The primary purpose of industrial compensation is to insure to the injured employee and those dependent upon him adequate means of subsistence while he is unable to work, and also to bring about his recovery as soon as possible in order that he may be returned to the ranks of productive labor. By this means society as a whole is relieved of the burden of caring for the injured workman and his family, and the burden is placed upon the industry. That the injured workman and his dependents may be cared for, compensation in the form of disability benefits is provided for by the act approximating the wages earned by the employee, and varying with the degree of disability and dependency. And, to secure the speedy return of the workman to productive employment, it is provided that medical and surgical services shall be furnished by the employer. This liability for medical and surgical services is not, therefore, a burden placed upon the employer as a penalty for any failure of duty on his part, but is merely a part of the whole compensation due the employee as the result of his injury. It therefore follows that the medical and surgical services contemplated and called for by the statute in question should be such as will tend to secure the return of the workman to productive employment. In other words—the treatment required by the statute is such as will reasonably and seasonably tend to relieve and cure the injured employee from the effects of the injury, and, manifestly, if the treatment practised and persisted in by physicians furnished by the employer, even though they be conceded to be skilled and competent in their pro-

fession, does not within a reasonable time effect a cure, and thereafter a course of treatment prescribed by other physicians procured by the injured employee does in fact seasonably effect a cure, then it cannot be said that the employer has furnished such medical and surgical treatment as was reasonably and seasonably required. The refusal, after more than three years of unsuccessful treatment, on the part of petitioner's physicians to operate, despite repeated requests to do so, which refusal extended over a period of nine months, during which time the injured employer continued to suffer, and his condition apparently grew worse, was tantamount to a refusal to furnish the treatment seasonably required by the statute. Before the injured employee would be entitled to compensation for expenses incurred in the treatment of him by a physician of his own selection, it would have to be shown that the treatment not only was a success, but that it was reasonably and seasonably necessary to cure and relieve the injured employee. In other words, the injured employee will be permitted, at the peril of having himself to pay the expenses of medical treatment, to secure the services of physicians other than those provided by his employer, and this peril will attach unless it can be shown from all of the circumstances of the situation, including the success of the operation, that his desire and decision to secure the services of other physicians was warranted."—*Union Iron Works v. Industrial Accident Commission*, 210 Pac. 411.

THE Supreme Court of Wisconsin, February 6, 1923, held that a school district which had established and maintained a manual training department in its schools can not be held liable for the injuries sustained by a pupil while attending the department from certain saws unguarded with proper safety devices and safeguards, although such guards are required by statute. "Manual training is now a constituent part of our system of education, and instruction in that branch involves the use of mechanical devices. But whether or not the doctrine of the non-liability of a school district should be changed is a matter which rests with the wisdom of the legislature, and not with the courts, and until such change is affected by a proper statute, we must consider it our duty to adhere to our former decisions and to persevere in favor of the non-liability doctrine."—*Sullivan School District No. 1 of City of Tench*—191 N.W. 1020.

THE contraction of typhoid fever by a hotel waitress from drinking water furnished by the hotel is an "accident" within the Workmen's Compensation Act according to the Supreme Court of Michigan in a decision rendered April 27, 1923.

It seems that the city supply of water in Saginaw was thought to be impure. In order to get a better quality the hotel put down an artesian well and piped the water throughout the hotel. January 15, 1922 the waitress entered the employ of the hotel and on February 25 became ill with typhoid. Later she made a claim for compensation before the Department of Labor and Industry. The court points out that "there could be no recovery for occupational diseases like lead poisoning, but it is evident that the occupation of head waitress in a hotel does not subject one to the liability of acquiring an occupational disease, and that typhoid fever is not an occupational disease." The court asks eloquently, "How could Miss Frankamp foresee that if she drank the water supplied to her in the hotel, she would be attacked with 'typhoid fever'?"

The evidence presented to the court certainly showed the probable origin of infection. The question turns upon the legal distinction between occupational disease and industrial accident. The illness, if directly traceable to employment as it was, should have been compensated undoubtedly but also if we confuse the medical findings, etiology and terminology, with legal technicalities the resulting conclusions may or may not be satisfactory. The supplying of water to the hotel employees and occupants was not an accident, the source of supply after the establishment of the well was constant. It was known that the city water supply was probably contaminated. It might reasonably follow that the artesian supply would bear analysis *before* the same was utilized in the hotel. After the plaintiff was taken ill such a sample of the water was sent to Lansing for analysis and was shown to be contaminated.

The question is raised as to whether logically there is any essential difference in the supply of water, air, heat, light, illumination, etc., from the point of view of the workmen. Should, for example, the inhaling of dust laden or impure air, the strain from defective lighting with their various end results be distinguished from the drinking of water demonstrably contaminated and the source of infection? The so-called "unforeseeability" it would seem was

as evident in one case as in another.—*Frankamp v. Fordney Hotel 193 N. W. 204.*

WHERE an employee broke his finger in the course of his employment and died from a dilation of the heart caused by an anesthetic administered to him for the purpose of performing a surgical operation on the finger, the Supreme Court of Pennsylvania, March 19, 1923, held that the causal connection between the original violence and the subsequent death was sufficient to authorize an award of compensation.—*Hornitz v. Philadelphia & Reading Coal & Iron Co. 120 Atl. 662.*

THE Supreme Court of Utah April 10, 1923 held that a strong and able-bodied workman who was wheeling a cart weighing over 1,200 pounds up an incline and who suffered a mitral lesion during his endeavor to prevent the cart from backing down the incline when it slipped was entitled to compensation for an injury by accident arising out of his employment. The question raised was whether the Commission exceeded its jurisdiction in making its decision. The Court held that the Commission did not exceed its jurisdiction.—*Cherdron Construction Co. v. Simpkins 214 Pac. 593.*

THE furnishing of decomposed and contaminated meat by an employer with the meals which it served to its employees at its boarding house, which board was charged to the employees by deduction from their wages, has been held by the Supreme Court of Washington, April 3, 1923, to be a sale of food within the statute forbidding the sale of adulterated or mishandled food or drugs. Adulterated food is therefore defined as including filthy, decomposed, or putrid animal or vegetable substances; or any portion of an animal unfit for food.—*State v. Grays Harbor Commercial Co. 214 Pac. 13.*

THE Supreme Court of Washington October 6, 1922, awarded compensation to a shingle sawyer who was transferring heavy blocks from a platform to a carrier and who sustained a rupture of a previously diseased appendix due to the pressure of the blocks when lifted as constituting an "injury."—*Shadbolt v. Department of Labor and Industry of Washington, 209 Pac. 683.*

A WATCHMAN who rode a bicycle in making his rounds was injured by falling from his bicycle, and in attempting to save himself by catching at a pile of lumber suffered an accidental injury. The Supreme Court of Michigan, June 5, 1922 upheld the finding of the Department of Labor and Industry, that the disability was due to an accident arising out of and in the course of his employment and not the disease with which he was afflicted. "The fact that the plaintiff was predisposed because of disease to this form of attack (to partial paralysis from a hemorrhage in his brain) has nothing to do with the question of what befell him, is to be regarded as an accident."

The award of the Commission was affirmed.—*Carvey v. W. D. Young & Co., 188 N.W. 393.*

THE Supreme Court of Kansas, October 8, 1922, held that a workman who was employed to haul ashes at a smelting plant, who became overheated at his task and drank ice water, which caused a congestion of the vascular system from which he died within one hour, was compensable as death caused by an accident arising out of and in the course of employment.

In the opinion of the Court "Here there was the added factor of the overheating, traceable to the workman's task of shoveling warm ashes on that unusually warm afternoon, and this brought about the condition which gave such sudden and fatal effect to the drinking of the ice water." This justified the holding that the incident was within the Workmen's Compensation Act.—*Gililand v. Edgar Zinc Company, 209 Pac. 658.*

Difficulties in Typhoid Testing

Difficulties with the Widal test have been reported by Pijper (*S. African Med. Rec., 1923, xxi, pp. 51-74*). In sixty-one cases in which verified typhoid bacilli were isolated from the blood, 117 samples were obtained. Forty-four of these gave a negative Widal. Testing appears to have been carried out very carefully.

Using a simple saline suspension of bacteria as antigen the author got 96 per cent positive results by complement fixation in the same series which gave only 62 per cent positive results with the Widal test. There were no positives in 60 control tests. (*Lancet, May 5, 1923, 5201, p. 913*).

SANITARY AND HYGIENIC ADVANCE

Dermatitis in Food Industries

Dermatitis occurring in a small group of workers employed in sorting out and packing dried foods is discussed by Russ (*Lancet*, Jan. 13, 1923, 5185, p. 77).

The irritation occurred on the palmar surface of the forearms and was of an uncommon type. Cultures were made, resulting in a fine, filamentous growth (resembling a mold) after fourteen days' incubation, inoculation with which produced a vesicular eruption, highly irritating and productive of a strong burning feeling. Cultures submitted to Prof. Massee were pronounced to be of a typical *Cercosporiella* form. This particular species has not previously been described and for it Massee has suggested the name *Cercosporiella vexans*.

No previous infection of the kind had occurred at the firm, which was long established, and antiseptic preventive measures controlled the trouble. Previously no germicides had been used in the lavatories, and only one nail brush had been in common use. The benches on which the workers sat had been covered with the sacking which had held the foods.

Cultivation from the foods, from decayed specimens, and from the sacks failed to reveal the source of the organisms. It was considered that the mold which caused the trouble had originated in the sacking, which came from the East.

Efficiency of Linen Weavers

The ventilation of linen weaving sheds is greatly complicated by the fact that the production of fine linen cloth is facilitated by a fairly high temperature and high degree of humidity. Weston (*J. Indust. Hyg.*, June, 1923, v. 2, p. 41) finds that "as a working maximum, a wet bulb temperature of 70 degrees F. should insure maximum production consistent with the comfort and health of the workers."

World's Largest Filtration Plant

"Detroit's new water purification works will be the largest single rapid sand filtration plant in the world," says Leisen (*Eng. News-Record*, May

17, 1923, 90, 20, p. 860). The plans provide for eighty 4 m.g.d. units, and in their entirety for 320-360 m.g.d., with facilities for meeting peak loads of short duration up to 400 m.g.d. Owing to the unstable nature of the soil every portion of the filter structure, including the filtered water reservoir, is being constructed on a pile foundation. This foundation added over a million and a half to the cost which exclusive of the pumping station approximates \$4,480,000.

Mosquito Identification Guide

A guide to mosquito identification for field workers engaged in malaria control in the United States has been prepared by Komp (*Pub. Health Rep.*, May 18, 1923, 38, 20, p. 1061). It contains brief descriptions of the form and markings of larvae, pupae, and adults found in this country together with keys for the identification of female adults and full grown larvae. Excellent illustrations accompany the text. It should prove very useful to the health worker whose knowledge of entomology is limited.

Value of Egg Yolk in Rickets

Hess has concluded that "egg yolks possess marked anti-rachitic properties for animals and for infants, far more than any other natural food stuff. This food is very well tolerated and can be recommended as a supplement to the dietary for even very young infants, much as orange juice is used to protect against scurvy. The yolk has also curative value but definitely less than cod liver oil" (*Proc. Soc. Exper. Biol. & Med.*, 1923, xx, 7, p. 369.)

Minimizing Traffic Accidents

Representatives of the manufacturers and users of traffic signals, of federal, and state governmental departments, of associations interested in the prevention of traffic accidents, and of the general public are at work, under the direction of the American Engineering Standards Committee, preparing a national code on the proper colors for traffic signals, which is expected not only to eliminate many of the irritations of motorists and the

operators of steam and electric railways, but also cut down the annual loss of life through traffic accidents. (*Science*, May 11, 1923, lvii, 1480, p. 550.)

Guyer on Hereditary Immunity

Guyer has stated that by inoculating successive generations of rabbits with typhoid bacteria he was able to develop an immunity so that rabbits of the fourth or fifth generation were able to overcome from thirty to forty times as many bacteria as the original rabbits could stand.

Prof. Guyer says, "the young may not only acquire immunity reactions from their mothers but may retain them sufficiently to transmit them in a measurable degree, without further immunization, to their offspring." (*Science*, May 11, 1923, lvii, 1480, p. x.)

Protection of Health in Boarding Schools

In a paper on the Protection and Development of Health in Boarding Schools (*J. A. M. A.*, May 5, 1923, 80, 18, p. 1310) Haven Emerson reports that in a privately endowed boarding school of the highest type with a uniform enrollment of four hundred boys between the ages of 12 and 18, an average of 3.55 per cent of all possible days of school attendance were lost on account of sickness during a three year period (1919-1920). Of all the days lost 74.5 per cent were lost on account of infections acquired through the respiratory tract.

The author lists the objectives to be attained by health supervision, the elements in a survey, the elements in a plan for health protection, and stresses the valuable contributions that can be made by those having an opportunity to conduct research in such controllable groups.

Two of the items listed in the proposed plan for health protection are, daily morning observation of every pupil by some competent person who knows how each one ought to look in health and daily inspection of the entire school by a physician for two weeks after holidays, or of individuals after absence from school for over night at any time.

The cost of infant weighing machines of sufficient accuracy for test feeding is prohibitive for many householders with the result that breast feeding may be discontinued when it could well be supplemented. The renting of such machines by a London firm has proved a great convenience. (*Lancet*, April 28, 1923, 5200, p. 880.)

Resistance and Diet

There has been but little experimental evidence to support the general opinion that a poor diet lowered resistance. Smith and Wason in a study of the serological factors of natural resistance in animals on a deficient diet (*J. Immunol.*, May 1923, viii, 3, p. 195) used rats fed on a ricket-producing diet.

They find that the "outstanding feature is a marked difference in the bactericidal titer; values for the most active sera among the rachitic rats being well below the lowest values secured for the normal animals.

"The complement titrations show but little variation, and there appears to be but little if any correlation between complementary activity and the bactericidal values of the serum."

Use of Fish in Larvae Control

Monroe states (*Am. J. Trop. Med.*, Jan. 1923, iii, 1, p. 21) that one may often find in the family water barrel innumerable larvae of *Aedes calopus* even though the barrel also contains a pair of fish. The average larvae consumption for the class of fish in general use for the purpose of mosquito control is about 150 per day. When conditions are as above it is not because the fish refuse to eat, but because of a mathematical factor (explained in the paper) that places the fish at a great disadvantage in the presence of a number of larvae beyond the limit of their possibilities to consume.

Study the pH of Natural Waters

Atkins has studied the pH of natural waters (*J. State Med.*, May 1923, xxi, 5, p. 223). They vary from pH 5.0, the reaction found with bog water, to pH 8.3 for a stream saturated with calcium bicarbonate supplies are normally between pH 6.8 and pH 8.0. With the exception of the extremes it would seem that natural waters are at a pH value favorable to the continued existence of *Vibrio comma* and the bacteria of the typhoid group. The author makes the suggestion that water may be made safe for drinking by rendering it as alkaline as pH 10.5 or thereabouts by adding ash derived from vegetable matter which is rich in the carbonates of potassium and sodium.

Training of Nursing Attendants

The Household Nursing Association of Boston, says Osgood, (*Boston M. & S. J.*, May 10, 1923, 188, 19, p. 732) has recently lengthened the preliminary

training for nursing attendants from six to nine months, in accordance with the recommendations of the Rockefeller Committee on Nursing Education. Before receiving their diplomas the attendants are required to work six additional months on private cases under the supervision of the association's full trained nurses.

This type of worker has been found very useful in bridging the gap between trained care of the private nurse and the care of visiting nurses. The work of the association receives the editorial commendation of the *Boston Medical & Surgical Journal*.

Reliable Disinfectant for Soda Waters Tumblers

Sayre reports (*Kansas State Board of Health, Bulletin No. 4, April 1923*) on a simplified formula for a reliable disinfectant bath for soda water tumblers. The simplified formula is as follows:

	Avoirdupois.	Metric.
Chlorinated lime.....	12 oz.	340 gms.
Sodium carbonate (U. S. P.)....	8¼ oz., 66 grains.	238 gms.

Triturate the chlorinated lime to a smooth paste in a mortar with 20 fl. oz. (600 c.c.) of water. Transfer the paste to a gallon bottle or flask, washing it from mortar with 14 fl. oz. (420 c.c.) of water. Dissolve the sodium carbonate in 17 fl. oz. (510 c.c.) of hot water and add the solution to the bottle containing the chlorinated lime. Shake thoroughly. If mixture becomes gelatinous, warm gently, strain through wet muslin until the liquid becomes clear. Wash with successive portions of warm water to make a total of 50 fl. oz. (1,500 c.c.).

	Apothecary's measure.	Metric.
Hydrochloric acid (U. S. P.).....	3 fl. oz.	90 cc.
Water.....	29 fl. oz.	870 cc.

Mix and stir well.

Solution No. 1.—Use 4 fl. oz. (120 c.c.) to each 3 gallons (11,352 c.c.), or 1 1/3 fl. oz. (40 c.c.) to one gallon (3,784 c.c.) of water.

Solution No. 2.—Use 1 fl. oz. (30 c.c.) of this solution to each gallon (3,784 c.c.) of the disinfectant bath in its final preparation for use.

Then mix solutions No. 1 and No. 2 in the above proportions.

A similar product prepared from a previously published formula (*Bulletin, May 1920*) has been used with great satisfaction for a number of years. The newer formula has been supplied at the request of druggists for a simpler method of preparation.

Facts relative to the present expenditures for the various phases of health work may be ascertained by consulting that section of the Report of the Committee on Municipal Health Department Practice dealing with Expenditures of Health Departments. (*Am. J. Pub. Health, June 1923, xiii, 6, p. 441.*)

Decline in Infant Mortality

The decline in the infant mortality in the U. S. Birth Registration Area from 1915 to 1921 has been studied by Woodbury (*Am. J. Pub. Health, May, 1923, xiii, 2, p. 377*). The authors statistical analysis shows the following decreases in this period:

Disease Condition	Percentage of Decrease
Gastric and intestinal diseases.....	34.6
Respiratory diseases.....	32.2
Malformations.....	10.0
Deaths in early infancy.....	10.8
Other communicable diseases.....	21.7
External causes.....	20.2
All other causes.....	23.5

Schick Test on School Children

Zinger reports (*Am. Dis. Child.*, May, 1923, 25, 5, p. 392) with many tables the results of Schick tests performed on more than one hundred and fifty thousand school children in Manhattan and the Bronx. The tables give percentages by type of reactions, by each year of age and by schools. The article gives a detailed picture of the present status of what is probably one of the most extensive public health activities ever undertaken by any municipality.

Concurrent Disinfection in Germany

A decree by the Prussian Ministry of Health formulates a new policy regarding disinfection following infectious diseases. In essence this provides for concurrent rather than terminal disinfection and has preference only to the contagious diseases specified in the Act of August 28, 1905, including tuberculosis, diphtheria, acute meningitis, scarlet fever, typhoid fever, dysentery, and trachoma. The Act of 1900 including plague, cholera, typhus, and smallpox remains in force with all provisions. (*Lancet, May 12, 1923, 5202, p. 965.*)

Test for Paris Milk Supply

Figures from the veterinary service of Paris and the Department of the Seine according to a Paris Correspondent (*J. A. M. A., April 28, 1923, 80, 17, p. 1255*) show that of 15,637 cows given the tuberculin test in recent years, 34.35 per cent gave a positive reaction.

Of fifty-nine specimens of milk examined:

75% contained over 10,000 bacteria per c. c.	
62% contained 50,000 bacteria per c. c.	
52% contained 100,000 bacteria per c. c.	
21% contained 500,000 bacteria per c. c.	
7% contained 1,000,000 bacteria per c. c.	

Excellence in Health Work to be Recognized

Announcement is made from the American Public Health Association that a series of awards is to be made by the association on the basis of attainment and advancement of community health service. Rating will be made on the basis of standards evolved by the Committee on Municipal Health Department Practice from a study of the practices of eighty-three of the largest cities of the United States. The first series of awards will be made to cities of a population of one hundred thousand or more which show the most nearly adequate community health service as of January, 1924. Similar awards will be made later on the basis of progress since January, 1924. Dr. C.-E. A. Winslow is chairman of the committee, which includes such distinguished sanitarians as Dr. C. V. Chapin, Providence, R. I.; Dr. Haven Emerson, Columbia University, New York City; Dr. Donald B. Armstrong, National Health Council, New York City; Professors Freeman and Frost, Johns Hopkins University, Baltimore, Md.; and Dr. L. R. Thompson of the United States Public Health Service.

Surgeon General Cumming of the United States Public Health Service has agreed to establish an office of administrative health practice under the direction of Surgeon Paul Preble to work in cooperation with the American Public Health Association.

Recreation Congress to Meet in Springfield, Illinois

The Recreation Congress will be held this year in Springfield, Ill., October 8 to 12, the sessions to be held in the state capitol building. Important among the topics to be discussed are athletics for girls and women, the national physical fitness campaign, adult recreation, recreation for colored people, and summer camps. Preliminary report will be made to the Playground and Recreation on the occasion of this meeting of the study of summer camps which is being conducted by L. H. Wier, J. W. Coverdale, secretary of the American Farm Bureau Federation, will address the congress on play in the small town and open country, and important hearings of recreation in industry will be developed by James Mullenbach, of Hart, Schaffner & Marx. Between eight and nine hundred delegates are expected to attend the meeting.

Protection Against Diphtheria

In guinea-pigs experimentally infected with diphtheria, Mackie has found (*J. Immunol., Jan., 1923, viii, 1, p. 35*) that normal serum (horse, ox, sheep, cat, rabbit, human) injected subcutaneously at the time of inoculation exerts a definite protective action. Two c.c. of normal horse serum may protect in this way against 12 m.l.d. of a *Corynebact. diphtheriae* culture. No protective action was found if the injection was delayed for two hours after the inoculation.

Hookworm Disease in Australia

Hookworm disease is an occupational disease related to two groups of Australian mines, reports Sawyer (*Am. J. Trop. Med., May, 1923, iii, 3, p. 159*). It is, however, absent from most of the mines, a few of which appear to be protected by the salinity of their waters.

Hookworm infestation cannot be regarded as an occupational disease related to the tilling of the soil in Australia. In rural districts it is largely limited to areas having over 40 inches of annual rainfall and involves chiefly the school-children.

American Public Health Association Meets in Boston

The American Public Health Association will hold its fifty-second Annual Meeting in Boston from October 8 to 11, 1923. Health Sunday will be observed in Boston churches on October 7. Registration will take place at the Copley Plaza Hotel, and meetings of the various sections of the association will be held in the Library and other near-by buildings.

Among the distinguished speakers who will address the General Session of the Association is Sir Thomas Oliver of Newcastle-on-Tyne, a noted specialist in industrial hygiene. Physicians in industry will also be particularly interested in the industrial hygiene sessions, at which several excellent papers on various problems in industrial hygiene are assured.

One of the most interesting sessions will be on Tuesday morning, when Professor C.-E. A. Winslow will present the Report on Municipal Health Department Practice, and announcements will be made concerning the award to cities for advancement in community service. The problems of the health officer of the smaller cities will receive attention at a round table being arranged by Dr. George C. Ruhland of Milwaukee.

The address of Dr. J. W. S. McCullough, chairman of the Public Health Administration Section, will deal with the whole subject of part-time versus full-time health administration. On Thursday morning a special session on Epidemiology is planned at which, among other speakers, Dr. Norman V. Lothian will describe the service of epidemiological intelligence and public health statistics of the League of Nations.

Dr. George E. Vincent, president of the Rockefeller Foundation, will address the second general session.

In previous years the clinic on printed matter has been largely attended, and this feature of the program will be repeated this year in the Section on Public Health Education and Publicity. The various other forms of communicating health knowledge to the public will also be discussed separately, and a special luncheon on motion pictures is being arranged.

The health exposition customarily held during the annual meeting will be held this year in connection with the Boston Health Show at Mechanics Hall, with the exception of the exhibit of the Book Department of the Association, which will be at the convention headquarters in the Copley Plaza Hotel.

Scientific trips to points of interest around Boston are being arranged, and the meeting will close with a boat ride down Boston Harbor.

Action of Vitamins

The mode of action of vitamins has been investigated by Cramer (*Lancet, May 26, 1923, 5204, p. 1016*) who states that they may be looked upon as "food hormones." Water soluble vitamin B is thought to stimulate the lymphoid tissue, while the fat soluble vitamin A has a stimulating effect on the intestinal mucous membrane, and also directly or indirectly on the formation of blood platelets.

Author's Correction

Dr. I. S. Falk wishes to correct an error in his paper "A Differential Analysis of the Reduction in the Death Rate" which appeared in the NATION'S HEALTH for July, 1923. On page 435 it will be noted that the cause of death titles 31-35 (inclusive) and 106 appear in both Groups I and III although they should have been listed only in Group I. This is due to an oversight and does not invalidate the data which were calculated without these duplications.

NEWS FROM THE FIELD

Children's Bureau Make Interesting Report

The Children's Bureau at Washington has made an arresting report of conditions in the beet fields of Michigan. It was found that many children as young as five and six were doing full-time work for the sugar companies. Housing conditions were deplorable, as many as ten persons were obliged to sleep in one ill-ventilated room. Some of the families were dwelling in caravan wagons; which offered such cramped quarters that as one child told the agent, the family "has to take turns going in as there isn't room for all of us at once."

Sanitation of Detroit's Swimming Pools

The epidemiologist of the Detroit Department of Health, George T. Palmer, reported in February that 15,000 people used the swimming pools of the city every week.

The results of bacteriological studies of seventeen pools for period from October to January, inclusive, may be summarized as follows:

Average of Monthly Median Total Counts (No. of bacteria per C. C.)	
Pools	
6	under 1000
4	1000-5000
7	over 5000
Average of Monthly Colon Counts per 100 C. C.	
Pools	
4	under 1.5
4	1.5 - 3
9	Over 3

Pay for Government Employees Reclassified

The Enactment of the Sterling Reclassification of work and pay of civilian employees of the Government, during the last days of Congress represents the culmination of several years of often embittered discussion and exacting study of perplexing problems of vital import to thousands of men engaged in the professional and scientific service of the Government.

The act embraces substantially the report of the reclassification commission of 1920. The salary schedules do not become effective, however, until July, 1924, and includes employees only in the District of Columbia. Interest now is transferred to the administration of the law and centers in

the work of the personal classification board in the allocation of government employees especially professional, scientific and technical workers.

Good Books for Workers in Health Fields

A selected list of books on public health has been issued by the National Health Council under date of April 1, 1923. This bibliography is intended to give to sanitarians and others interested, much needed information as to the best books on the various phases of public health. The 175 books included are listed according to authors under fifteen headings: Administration and General Public Health, Cancer, Child and Maternal Hygiene, Communicable Diseases, Foods and Nutrition, Health Education, Industrial Hygiene, Laboratories, Mental Hygiene, Personal Hygiene, Public Health Nursing, Sanitary Engineering, School Hygiene, Social Hygiene, and Tuberculosis. The publisher, price, and year the book was issued are also given and a list of public health magazines is appended. Single copies of the bibliography may be obtained from the National Health Council, 370 Seventh Avenue, New York City.

Roentgenology and Radium Therapy

The report of the committee of the American Roentgen Ray Society appointed to study the question of the danger from high tension shock and to formulate safety recommendations applicable to high voltage therapy is published in the March issue of the American Journal of Roentgenology and Radium Therapy. It is recommended that in view of the rapidly changing principles in the application of x-ray and in the manufacture of apparatus, that the investigating committee should be a standing committee to report on individual problems as they arise.

The National Narcotic Conference held in Washington May 4 asked that Federal control of the drug traffic be divorced from the prohibition bureau. The present appropriation of \$750,000 is declared entirely inadequate and the number of field agents should be

increased from 163 to five hundred. A world-wide agreement is held essential to effective control of the traffic.

"To Make Georgia a Better Place to Rear a Child"

Twenty-eight social service agencies and an advisory section of one hundred or more lay members, a budget of \$7,500 and a permanent secretary constitute the machinery recently set to work in Georgia "to make Georgia a better place to rear a child." Two study committees are at work, one on the codification of children's laws, and the other on the treatment and prevention of crime.

Census of North Carolina's Crippled Children

Seventy-nine counties reporting in a cripple census week held in North Carolina up to December 15 had accounted for nearly four thousand crippled children. On the basis of classifications made possible by the returns of the census corrective measures and vocational rehabilitation will be undertaken on a wide scale. Treatment will be instituted at the Orthopedic Hospital at Gastonia, local clinics will be provided for cases not requiring hospital care. The chief need is a convalescent vocational home.

India Makes Plans to Eradicate Plague

The public health commissioner of British India is reported in the New York Times as having announced a rise in mortality due to the plague which began last December and which up to March accounted for 36,900 deaths. The wholesale destruction of rats is recommended, and careful storage of grain products. Thus far an organized attempt to stamp out plague in India has not been made.

American Law Institute Receives Large Sum

The Carnegie Corporation has given a fund of \$1,075,000 to the American Law Institute recently organized for the purpose of restating and simplifying the law. The work to be undertaken in the codification of the common law is the most ambitious program ever assumed by the legal profession in any country. The fact that something like ten thousand new laws and as many or more new interpretations have become a part of court records during the past five years indicates the necessity which urges the leading judges and lawyers to the task.

Joint Committee for Prison Investigation

New Jersey investigators who have just completed a survey of penal institutions make recommendations for prison reforms which have to do chiefly with administrative details. It is suggested that prisons be administered by a joint committee of not more than six members, this committee to act as a clearing house for information and recommendations of sub-committees whose duties would be concerned with the specific problems involved. Most of the inefficiencies responsible for present prison conditions are chargeable, says the report, to the lack of time for the prison board as a whole to study carefully and fully understand all the complicated questions which come before it.

A portion of the report having to do with prison health was printed in the April issue of THE NATION'S HEALTH.

Another recommendation is that some form of supervised physical exercises and recreation should be provided for idle prisoners. Further development of the educational system of the prison, with particular emphasis upon Americanization and library work; utilization of the repair shops for purposes of industrial instruction, and the establishment of a barber's school are also recommended.

Investigations on Household Refrigeration

Dr. M. E. Pennington, Chicago, with the active cooperation of home economics educators throughout the country, will conduct a series of important investigations on problems connected with household refrigeration. Reports of findings will be issued from time to time and the Bureau will serve consultants on individual problems. The project is conducted under the auspices of the National Association of Ice Industries.

Hardness of Public Water Supplies

Analysis of water from the public supplies of more than three hundred large cities of the United States, as reported by W. D. Collins before the Philadelphia Section of the American Chemical Society, shows that the average hardness of the surface water supplies is 85 and the ground water supplies is 226. Surface supplies are used by thirty-four of the thirty-nine million inhabitants of these cities.

If the hardness of a water, expressed in the ordinary way as equivalent calcium carbonate, is less than 50 parts per million, comparatively few persons notice the hardness in ordinary use. Such water may be called soft.

If the hardness is between 50 and 100 parts per million, most persons would notice it but would not be greatly troubled by it. Practically all industrial plants, where hardness is detrimental, would under such conditions find it profitable to soften the water. Water between 100 and 200 parts per million is hard without any qualification. Treatment is profitable for household use and for nearly every use where hardness affects the value of a water. Very few waters for public use have hardness over 400 parts per million.

The hardness of water from Lake Michigan used in Chicago is about 130 parts per million. The average for the states along the Atlantic Coast and the east coast of the Gulf of Mexico is less than 55 parts per million. The average of the four large supplies of Florida is 296. Public supplies in the central states are all hard or very hard, and a number of them are softened in connection with their filtration plants.

Problems in Industrial Pension Systems

Those who urge industrial pension systems as the one effectual means of ameliorating the condition of workers grown old in service find an interesting problem in the dilemma of participants in the pension fund of Morris & Co., recently absorbed by Armour & Co. The Morris pension fund was established in 1909. Under the new Armour régime Morris employees who were more than forty-five years of age in 1909 are not eligible for participation. The contributions of individuals in this class will be returned with interest. Some five or six hundred employees who have spent most of their lives with that organization thus find themselves in their uncertain years with no protective agreement in the Morris-Armour transfer to cover their rights. A suit being brought by four hundred former Morris employees against Armour & Co. on this point will be watched with interest.

Iowa and Oklahoma are among the recent states whose legislatures have accepted the provisions of the Shepard-Towner law for work in maternal and infant welfare.

Surveys Essential for Rural Cooperation

A study of cooperative laundries in the United States is reported in the May issue of the *Journal of Home Economics* by Ruth Van Deman. Of the five cooperative laundries in the United States only two have been running long enough to be considered on a stable financial basis. The conclusion is reached that the rural community is the logical field. The article delineates the requirements of the preliminary survey essential to establishing a successful community enterprise of this kind.

Alternate Working Periods for School Children

The Cape May, N. J., school board has organized a council of athletics, consisting of two members of the board, two of the faculty, two of the alumni association, five students, and the superintendent of schools.

Twenty-five states have adopted laws requiring part-time or continuation schools and it is predicted that practically every industrial commonwealth in the country will take steps in this direction during the next five years. Baltimore, Md., has evolved a "two-boy work-school" program by which two boys or two girls will be employed on a single job and while one boy or girl works for a period of one or two weeks, the other one will be in school. At the end of the period they change places. The money earned during the period of work will be sufficient to keep the child in school during the alternate periods. The program includes a scheme of continuous counsel with the children and such health supervision and inspection of working conditions as will safeguard the present and future usefulness of the youthful workers.

Canadian Sanitation

The Federal Department of Health of Canada has just issued a brochure on Sanitation dealing with the subject of sewage treatment for isolated houses and small institutions where municipal sewage system is not available. The urge for such information has been so insistent that, having in mind the health and welfare of the people, it was considered advisable to have the subject dealt with in a scientific and thoroughly practical manner. The publication is generously illustrated, emphasizing the application of the advice given.

This publication can be obtained free on request from the Deputy Minister, Department of Health, Ottawa.

Methods of Handling Various Materials in Industry

Safe Practices Pamphlet No. 54 entitled "Handling Material" has just been published by the National Safety Council, 168 North Michigan Avenue, Chicago. Handling material is generally recognized as one of the greatest safety problems in industry and according to state reports handling material by hand causes more accidents than all machinery. The pamphlet is divided into the following main divisions: Power Trucks, Hand Trucks, Piling Material, Handling by Hand and Safe Habits of Work, each of which is again subdivided into paragraphs dealing with the different types of equipment used and the different methods employed in handling various types of material. The pamphlet is freely illustrated with photographs and diagrams. A large number of industries are covered and owing to the fact that handling material is common to every industry, the pamphlet has an unusually wide range of usefulness. The experience of many members of the National Safety Council was contributed in the preparation of the pamphlet and the assistance of a committee of seventy-five safety engineers was employed in editing and revising the material.

Dispensary and Out-Patient Work of Hospitals

Conferences intended especially for persons engaged in dispensaries and out-patient departments of hospitals have been arranged by the United Hospital Fund of New York City to be held at the New York Academy of Medicine. The subjects announced for discussion include the admission of patients, records and statistics, cooperation between dispensaries and other agencies, clinic management, and follow-up work.

State Aid for New York Special Classes

The Antin-Cole bill recently passed in New York provides state aid for teachers of special classes of backward children throughout the state. The development of adequate provision for special classes makes it possible for the first time for the mental deficiency program to begin its efforts in childhood, the period when such measures may be expected to reach their fullest possibilities. The Committee on Mental Hygiene of the State Charities Aid Association cooperated with the Department of Education in

introducing the measure and in organizing state wide support for it.

Board of Education not Responsible for Accidents

Decision has been rendered in favor of the board of education of the city of Fargo, N. D., that in providing playground apparatus as authorized by law for the health and physical education of pupils, the board acts purely in a governmental capacity and is not subject to suit, either in an action for damages or otherwise for the death or injury of a pupil when struck by heavy apparatus in operation on the school grounds.

The annual meeting of the Home Economics Association was held in Chicago July 30 to August 3. The program announced showed seventy-two names on the program, fifty-five of them being home economics people in active positions in home economics organizations, and seventeen men and women in related fields. Hotel headquarters were at The Windermere East.

Ill Health a Factor in Mothers' Pensions

A study of 53 fatherless families in Dallas County, Texas, conducted by the Civic Federation of Dallas, with a view to determining the value of the local system of widows' pensions shows that in 34, or 66 per cent, of the families studied, either the mother or children or both were in ill health. In 9, or 17 per cent of the families, both mother and children were ill. "Ill health is a serious factor in the economic life of the struggling family."

Medical Society Supports Georgia Clinics

The Medical Association of Georgia expects to undertake a state wide campaign for the control of tuberculosis, to hold clinics, and to teach physicians the methods of early diagnosis. They expect also to offer concrete help to county and state authorities in the campaign against malaria and hookworm.

Hospital Service in New York City

William Fellowes Morgan, president of the United Hospital Fund, reports that 201,271 patients were cared for in the fifty-eight hospitals of the fund last year. This is an increase of 5,990 over the previous year. Forty-seven of the hospitals are in New York and eleven in Brooklyn. The pa-

tients comprise medical, surgical and accident cases and all classes of ailments and diseases.

St. Louis Repeats Free Clinic for Crippled Children

The St. Louis Medical Society has elected to repeat the survey made in 1922 of crippled children in order to ascertain how many of these children are not being treated because of inability to pay. Permits will be issued to such children to admit them to a three day clinic to be held in their interest at the offices of the medical society in St. Louis.

Rural Communities More Susceptible to Diphtheria

In New England, at least, the susceptibility to diphtheria is higher among persons living in sparsely settled or rural regions than it is among those living in cities; and it is much higher among the well-to-do than among the poor, and among the native born than among the foreign born. Such are the conclusions reached by Dr. C. W. Kidder, of the U. S. Public Health Service, after an investigation, recently completed, in the Eighth Sanitary District of Vermont, which has a population of 35,000.

The Schick test was administered to a little more than 2,000 teachers and school children whose parents requested it. Of these about 1,500 were found to be susceptible to the disease; and their immunization with toxin-antitoxin was at once begun.

Course in Physiotherapy to be Open to Women

The next course of instruction in physiotherapy to be given at the Walter Reed General Hospital, Washington, will begin Oct. 5, 1923, and continue four months. It is open to women who have had at least two years' training in an approved school of physical education. For information, apply to the commanding officer, Walter Reed General Hospital, Washington.

The New York State Department of Health has issued an enjoinment on the method of the city of Watervliet which requires every person or corporation selling milk from a wagon or vehicle to expose a metal plate denoting the grade of milk which is being sold. The plates read: "Health Department-Grade A, Raw," "Health Department-Grade B, Pasteurized," etc. The plates are placed upon the vehicle under the direction of the health commissioner.

Chair of Nursing Endowed at Columbia

Through the foundation of a chair of nursing by Mrs. Helen Hartley Jenkins, of New York, Miss Adelaide Nutting has been made professor of nursing at Teachers' College, Columbia University. This is reported to be the first endowment of its kind.

Report on New York Farms and Markets

A report just issued by Berne A. Pyke, New York State Commissioner of Farms and Markets, states that the cost of maintenance of state institutions is greatly reduced by the forty farms operated for the purpose of supplying food consumed by the inmates. Only four out of forty failed to show a profit.

Increase in Crossing Accidents

If the crossing accident rate reported for June by the Pennsylvania Railroad during the month of June indicates the average trend throughout the country, the showing for the present summer will be the most deplorable yet recorded, says the *New York Times*. The month of June showed an increase of 115 per cent over the same month in 1921. Analysis of the causes emphasizes the dangers of recklessness on the part of drivers.

Workers More Efficient in Low Temperature

A report has been issued on "Variations in Efficiency in Cotton Weaving" by the Industrial Fatigue Research Board (England), based principally upon hourly output readings taken on about six hundred looms over a period of one year. The study indicates that a remarkably uniform standard of efficiency is maintained. Owing to the large mass of data involved, individual and chance variations are practically eliminated and the general tendencies indicated may therefore be regarded as real. Among the facts that may be so accepted is the statement that at temperatures over 75 degrees F., productive efficiency tends to fall owing to fatigue on the part of the workers; also, that during the periods of artificial lighting the output may be reduced by 5 per cent.

New York City has passed an ordinance requiring every physician and every dentist using x-ray machines to obtain a permit from the Department of Health.

Transitional Executive Committee Appointed

The English Ministry of Health, with the concurrence of the Rockefeller Foundation, has appointed a transitional executive committee: Mr. Neville Chamberlain, chairman, and Mr. L. G. Brock of the Ministry of Health, secretary, whose functions shall be to appoint a director to arrange for the amalgamation between the School of Hygiene and other institutions working in similar or closely related lines.

Extent of Insurance Legislation

That the public intends eventually to become the arbiter in the kind of insurance which shall be written in the country is evidenced from the fact that insurance bills, after but a few months of legislative activity, are reported by the *National Underwriter* to number 1,700. In 1921 the Insurance Federation of America was called upon to analyze, and interpret 1,471 bills introduced into forty-four legislatures.

Manitoba Co-ordinates Child Welfare Work

Manitoba's Child Welfare Act of 1922 coordinates the work defined by several previous laws which were administered through different departments. The Children's Act, the Infant's Act, and the Illegitimate Act are all repealed, leaving the written legislation affecting children in general consolidated in the new law and the Juvenile Delinquent's Act.

Manual Training Benefits Disabled Veterans

A statement recently issued by the U. S. Veterans' Hospital 81, in the Bronx, shows that of 1,619 patients admitted during the first year, 1,081 were discharged after periods of treatment varying from weeks to months. The high percentage of cures is attributed to the beneficial effects of training, academic and manual, fitted to the needs of the patient and occupying him at all times.

Yellow Fever Eradicated from Peru

Dr. Henry Hanson, director of public health for the republic of Peru announces that the country is free from yellow fever for the first time in history. Practically the whole western coast of the Western Hemisphere may be said to be free from this disease. (*J. A. M. A.*, Feb. 10, 1923, *lxxx*, 6, p. 412.)

Osteopaths Adopt Anti-Drug Pledge

The delegates of the twenty-seventh annual convention of the American Osteopathic Association, at their closing session in New York City, July 7, passed a resolution pledging themselves to "help all legitimate efforts for the suppression of traffic in narcotic drugs."

Workmen's Compensation Applied to Injured Children

The annual report of the Indiana Industrial Board shows that out of 859 cases of industrial accidents to minors investigated by the department, 418 involved children employed in violation of the law. The *American Labor Legislation Review* brings out the fact that in most states compensation laws have been so framed as not to apply to children illegally employed. In Wisconsin, Oregon and New York minors illegally employed are given a greater indemnity when injured than if legally employed. Under the Wisconsin law, treble damages are awarded.

Great Variations Registered in Death Rates from Heat

For no other single cause of death has there been such a marked variation in the death rate as that shown for heat and sunstroke, as recorded among industrial policy holders of the Metropolitan Life Insurance Company. In 1911, 6.7 policy holders per 100,000 died from effects of heat, while in 1920 only 0.2 per hundred thousand died from this cause. An even greater variation occurs for the United States Registration Area, 1900 to 1920, inclusive. Here the maximum heat fatality rate was 12.8 per hundred thousand in 1901, and the minimum 0.3 in 1920, that is, approximately forty-three times as many heat deaths the maximum as the minimum year. The lowest rates usually fall in the mountainous states and in Washington, Maine, and Vermont. Above-average rates are registered, not in the southern states, but particularly Michigan and Wisconsin of the East North Central states; all of the Middle Atlantic states (New York, New Jersey and Pennsylvania); Maryland in the South Atlantic region; and Missouri in the West North Central section.

The United Hospital Fund of New York City announces that it costs the city \$54,000,000 a year to be sick, and that 180,000 persons on an average are on the sick list each day.

HEALTH PUBLICATIONS REVIEWED

A Parody Sport Book

In "A Parody Sport Book," by Clifff Goldsmith, "Professor Happy" of the American Child Health Association, tells in words and pictures which will delight all boys, how to play the game of health from "Water Polo, the favorite Sport of Bathtub Bay" which "should be played every morning at son rise or daughter rise, as the case may be" to "Evening Baseball, the game that made the White Pajama Twirlers famous over night." To his convincingly sporty text, Professor Happy has added equally convincing illustrations by Clive Weed, and signed photographs of such sporting world heroes as Charles Paddock, Bobby Jones, and Bo McMillin, with a full page photograph and personally signed letter from Ty Cobb which introduce the *Sport Book*.

Health Education Division, American Child Health Association, New York City, 1923.

Exercise in Education and Medicine

The re-edition of R. Tait McKenzie of his text on "Exercise in Education and Medicine," permits the inclusion of recent developments and experiences gained through the war. The extension of physical education into schools, municipal playgrounds, and recreational centers; the wider use of athletic games; the devices for muscular re-education; the use of exercise in cardiac involvements are all matters of general and immediate concern. The book is carefully illustrated with an abundance of suggested exercises.

W. B. Saunders & Co., Philadelphia, 1923.

Employee Welfare Work

Defining welfare work as voluntary effort to improve living and working conditions of employees beyond the requirements of the law, L. A. Boettiger, professor of sociology, Lawrence College, has produced in "Employee Welfare Work" a comprehensive survey which sets forth the characteristics of typical organizations. The evolution of the several definite systems of welfare arrangements constitutes the historical background of the problems in this field that are engaging employers and managers today.

The incongruous medley of motives accounts for the confusion in terminology, and for the great variety of reactions to welfare work, but the movement is certainly to be credited with accumulating a constantly increasing body of knowledge respecting the application of psychology, physiology, business and community organization to the problems of production. Conditions are better, wages are better, and security is better because of them. Employers' welfare work is best interpreted "as the direction of inventive effort to the organization of personnel for productive purposes." Evidences of general interest are given in the growing movement for courses on personnel administration, industrial relations, employees' welfare work, and employment management in the leading universities and colleges, and in the testimony of financiers and great employers of labor that "welfare work pays."

The Ronald Press Company, New York City, 1923.

Diet and Race

A series of anthropological essays under the title, "Diet and Race" is brought out by F. P. Armitage, director of education for the city of Leicester. His thesis that the diet consumed over many generations influences racial characteristics is presented under three sections dealing with physique, color, and cranial form.

Physique is an individual characteristic, but the small stature of Chinese and Japanese, the sturdiness of the Englishman, the supple leanness of the Arab, he considers as due to the diet. The matter of color regarded as controlled by the amount of salt, is interesting but will not bear as close analysis as other parts of the book. The anatomical considerations as to classical form are not so fully worked out.

The book is a scholarly presentation that is frankly incomplete and the suggestion of the author is that the multitude of present day dietary studies be considered with reference to racial background as well as in regard to adequate nutrition of the individual.

Longmans, Green & Co., New York, 1922.

Children's Welfare Federation

A directory of the child welfare organizations of New York City has just been published by the Children's Welfare Federation. This directory gives information regarding all of the work which is carried on for the benefit of children.

Interesting statistics have been tabulated from the data collected for this directory:

There are 106 health stations operating clinics for babies, pre-school age children and school children who are suffering from malnutrition.

There are thirteen different divisions in the city departments whose functions include some type of child welfare work.

One hundred and twenty day nurseries offer protection for children whose mothers must go to work.

There are 132 institutions and homes ready to shelter children who must seek protection outside their own family circle.

Ninety-nine settlement houses are carrying on some kind of child welfare activity.

There are forty-eight shelters prepared to give temporary care to mothers, babies and children who are temporarily stranded.

One hundred and nineteen organizations are interested in providing vocational guidance and employment for boys and girls, and twenty-four organizations are granting scholarships.

There are in the vicinity of New York City, convalescent and fresh air homes operated by 110 different organizations. In some instances several homes are operated by one group.

Children's Welfare Federation, New York City, 1923.

The second report of the Association for the Prevention and Relief of Heart Disease is an account of not inconsiderable achievement. Particular interest centers in the establishment of forty-three out-patient classes devoted to the diagnosis and treatment of heart disease, the opening of convalescent homes to the heart cripple, the work in the public schools, and work connected with suitable industrial placement for those with damaged hearts.

Social Work in Hospitals

A revised edition has been issued of "Social Work in Hospitals; a Contribution to Progressive Medicine," a standard text on the history, development, and problems of hospital social work. It has a place in every library and in the hands of every public health worker in dispensaries, hospitals, and institutions.

Russell Sage Foundation, New York City, 1923.

Krause Issues Two Books on Tuberculosis

A number of illuminating essays and addresses by Dr. Allen K. Krause have been collected in two little volumes: "Environment and Resistance in Tuberculosis," and "Rest and Other Things," which will be hailed with appreciation by all students of tuberculosis.

The first volume contains an illuminating analysis of the factors at work in environment and resistance, emphasizing the complexity of the subject and suggesting particularly what might be called the chance factors of time and place as they control the result of the struggle between the invading germ and the resisting host. Dr. Krause's analysis of the subject of allergy and specific immunity will be found particularly helpful.

The second book deals more particularly with the practical problems of tuberculosis control emphasizing the author's view that "rest remains the sovereign remedy for tuberculosis." Artificial pneumothorax "the one effective weapon against advanced pulmonary tuberculosis which the period since the discovery of the tubercle bacillus has disclosed" is treated of course as a special case of rest. From the standpoint of infection Dr. Krause is a strong believer in outdoor indirect sputum infection as the most important quantitative factor and he dwells at length on the important theoretical results obtained by the use of the Pirquet test, which he classes with Laennec's promulgation of the unity of phthisis, Villemin's discovery of the infectiousness of tubercle and Koch's revelation of the bacillus as the quartet of really great episodes in the history of tuberculosis.

We can never have too much of Dr. Krause's clear vision and eloquent interpretation. It is to be hoped that his series of historical studies of tuberculosis published some years ago in the *Journal of the Outdoor Life* may soon be given to us in book form.

Williams & Wilkins Company, New York, 1923.

Merchant Seamen: Their Disease and Welfare Needs

The attempt to improve sanitation and working facilities on land have not been reflected in the control of ships according to this author. "The miserable pay, and that not due till the end of the voyage; the atrocious conditions of dirt and over crowding, with bad ventilation or none; the lack of facilities for keeping personally clean; the badly cooked, badly served, monotonous food; the hard work and long hours at sea—" are things we know comparatively little about. The book under the above caption by W. E. Home, is brief, concise and an extremely interesting and illuminating discussion of the employment conditions of sailors, the various merchant shipping bill requirements, including a notation of the accommodations on various boats, and the diseases of merchant seamen.

E. P. Dutton & Co., 1922.

Food for the Diabetic

Diabetes as a disease primarily characterized by the inability to handle certain foods, and one in which any successful management on the part of the physician presupposes an intelligent co-operation of the patient is amply discussed in a really valuable book under the above title by Mary Poscoe Huddleson. The book gives the elements of the dietetic treatment of the disease, supplies food tables with interchangeable quantities in units of household measurement, supplies suitable recipes and a constructive basis for menu planning that emphasizes possibilities of variation rather than the usual discouraging dead line of inhibitions. The book is of real value in the hands of the patient. Dr. Nellis F. Foster says in the introduction, it is the best manual he knows for the teaching of diabetics.

The Macmillan Company, New York, 1923.

Penal Discipline

In "Penal Discipline" Mary Gordon has brought out a very interesting narrative of her thirteen years of experience as a prison inspector, her study and analysis of the inmates and their difficulties and of administrative procedures and results, with suggested bases for reform. The distinction between prostitute and common prostitute, the discussion of prison types, and of the practice of tattooing are very unusual in the type of material presented.

E. P. Dutton & Co., New York City, 1922.

Employers' Associations in the United States

In "Employers' Organizations in the United States" Clarence E. Bonnett has made a study of typical associations and has drawn together the data relating to employer's groups which he defines as those composed of or fostered by employers and seeking to promote the employer's interests in labor matters and which of course may be formal or informal in character. The development, history and methods of these associations are more or less familiar to any student of labor problems, but a correlation and interpretation of their activities and interests is very valuable. The author has divided his subject matter into certain trade groups under the associations, in the iron and steel industry is discussed the Stove Founder's National Defense Association, the National Founder's Association, the National Metal Trade's Association and the National Erector's Association; the associations in the building industry, the printing industry and in fields of propaganda, legislation and litigation, such as the National Association of Manufacturers among others, their principles, purposes, propaganda, publications, methods, obligations, relations and funds are pointed out in each case. The author offers no immediate solution to our difficulties, shows the respective rise and fall of power; and shows further that the conflict should be controlled to avoid increasing intensity and complications.

The Macmillan Company, New York City, 1922.

The Transactions of the Thirteenth Annual Meeting of the American Child Hygiene Association, held in Washington, D. C., October 12 to 14, 1922, just issued, contains papers and discussions by authorities on maternity and child welfare which should prove a valuable reference in the health library. It is available through the Child Health Association, at their Washington office.

Public Health Bulletin No. 134 offers the suggestions of authorities on effective organization and conduct of nutrition work in rural districts, towns, and cities of 25,000 to 30,000. It is especially helpful in its plan for preliminary surveys to determine the size of the problem and to secure the co-operation of all local agencies both in conducting the work and in thorough-going follow-up work in the homes.

Education and Training for Social Work

This report on "Education and Training for Social Work," by James H. Tufts was undertaken under the auspices of the Russell Sage Foundation on the request of the Association of Training Schools for Professional Social Work. It is primarily a discussion of the problem of education and training divided into two parts, (1) the field of social work and (2) the problems of education and training. The purpose and organization of professional schools, their location, requirements, curriculum, methods of instruction and fellowships and scholarships are all treated very frankly and thoughtfully. The establishment of social work on a professional basis will increasingly require carefully selected personnel and the thoughtfully developed curriculum. The present book is a very valuable contribution in view of the general status of training school affairs.

Russell Sage Foundation, New York City, 1923.

The Meaning of Child Labor

The problems of adjustment and enforcement of child labor legislation keep the program of reform constantly before us. In his recent book on "The Meaning of Child Labor," Raymond G. Fuller declares that an adequate outline of child labor would include its direct effects on physical, mental and moral hazards; its indirect effects or the loss of school, play, etc.; substitutes for child labor such as play, schooling and suitable work; and methods of reform. The book though small and concise offers a very satisfactory statement of the general problem and its ramifications such as illiteracy, delinquency, truancy, etc.

McClurg, Chicago, 1922.

Women Workers and Society

A re-edition of "Women Workers and Society" has been brought out as a part of the National Social Science Series covers some of the problems involved in the employment and enfranchisement of women. The material included is not new but very clearly and simply put.

McClurg & Co., Chicago, 1923.

National Health Insurance in Great Britain

Henry J. Harris is responsible for the compilation of U. S. Department of Labor Bulletin No. 312 on "National Health Insurance in Great Britain, 1911 to 1921." The results

reported are principally valuable because they represent the most extensive health data on any population in the world, the number of insured persons in England and Wales in 1913 was about 11,211,000, representing about 85 per cent of the insured population studied in the report. A wide variety of industries, and also the professions, is represented. Recommendations are made for simplifying the administration and correcting abuses, but it is interesting to note that the consensus of opinion is that the actual working of the plan was of distinct value to the persons insured, and that all recommendations are in the direction of extending and improving the system. The present report is stated to bring down to date the history of health insurance in Great Britain first reported in the twenty-fourth annual report of the U. S. Commissioner of Labor in 1909.

Syllabus on Health for Newark Schools

The State of New Jersey, in its compulsory physical education statute, provides that parallel with the regular exercises and games, correction of posture and instruction in personal and community health and safety shall be a part of the course of study.

On October 28, 1920, the board of education of Newark adopted a "Syllabus on Health" with the result that the children are really being trained in health. David B. Corson, the superintendent of schools, states that "the work is having a marked effect on the appearance of the children and on the general state of their health."

This fifty-six page booklet gives directions for the organization and functioning of health leagues for the classrooms and a health association for the school. It outlines health instruction for grades one to six, inclusive. Starting with a tooth brush drill and song, morning hygiene drill, and Health Fairy Don'ts for the first and second grades the course is expanded till sixth year pupils are instructed in digestion, circulation, how disease germs spread, insect enemies, etc.

This instruction occupies fifteen minutes a day for ten weeks of each term.

Milk Consumption is Increasing

During the year 1921, the consumption of milk according to the United States government, increased from 43

to 49 gallons per person. This is an increase of approximately 14 per cent.

Back in the year 1890, according to the government statistics, the consumption of milk was only twenty-two gallons per person and in 1899, nine years later, the consumption of milk had increased only one gallon during the entire nine years, which is at the rate of only $\frac{1}{2}$ of 1 per cent per year.

1890.....	22 gal.
1899.....	23 gal.
1917.....	42.4 gal.
1920.....	43.0 gal.
1921.....	49.0 gal.

As the twentieth century was ushered in, the consumption of milk began to increase and it has been gaining momentum ever since.

The increase in milk consumption during the last two years is especially noteworthy.

Health Examination Movement

(Continued from page 611)

were classed as capable of undergoing physical exercise, not involving strain, 31 to 32 per cent had marked physical disabilities, and 10 per cent were totally unfit.

The only instance where fairly extensive physical examinations of the general population have been made in an American community seems to have been in Framingham, Mass. In the year 1917, during the famous five year community health and tuberculosis demonstration conducted there under the direction of Dr. D. B. Armstrong, nearly five thousand citizens of the town were given medical examinations. Of the 4,473 looked over, 3,456, or 77 per cent, were recorded as "ill." Of those in industrial age groups, 71 per cent were classed as "ill." Of the defects recorded, 67 per cent were directly preventable, 22 per cent partially preventable, and the remainder, or 14 per cent, not preventable. The actual medical examination discovered just twelve times as much illness as had been brought out by a health census carried on by nurses and insurance agents who made a house to house canvass, asking as to known illness. It is interesting to consider in this connection that sickness surveys of 579,197 white employed persons conducted by the Metropolitan Life Insurance Company in several communities by the canvassing methods showed a disabling sick rate of 18.8 per 1,000. This rate may have been only one-twelfth of the real total.

When persons of very low economic status are given physical examinations, as would be expected, a greater number of defects are found than in the more favored classes. Data recently made available by the Committee on Dispensary Development of New York show that of 872 persons of low economic condition, about 70 per cent of whom were foreign born, who were examined, only 20 or about 2 per cent, could be regarded as normal, requiring no treatment or health direction. All of these people, consisting of 113 men, 413 women, and 346 children—42 per cent of them Italian—were examined at four health centers in lower New York City. Out of a total of 903 examinations made at various times, 603 or 62 per cent required medical treatment, 343 or 35.4 per cent needed hygienic advice but no treatment, and 24 or 2.4 per cent were normal.

So much for the necessity of health examinations. If anyone had any doubts at all, this summary of defects found by actual experience in examining apparently normal individuals should dispel them forever. The question arises, though, as to what are the results from health examinations. Here again, we have an answer. The Metropolitan Life Insurance Company since 1914 has offered to its policy holders free annual medical examinations and has contracted with the Life Extension Institute to make them. About a hundred thousand persons have been eligible to have these examinations and about seventy thousand have availed themselves of the opportunity. A careful survey of the records of 5,987 persons examined during the first two years (1914 and 1915) has been made and some remarkable facts brought out.

Whereas in five years 412 of these persons should have died according to the American Experience Table, actually only 217 died. In other words, the death rate of this selected group of nearly six thousand persons who thought enough of their physical welfare to have a health examination was only 53 per cent of the American Experience Table and 72 per cent of the American Men Table. In one year (1915-1916) those examined showed a mortality of only 39 per cent of the American Experience Table, while ordinary policy holders showed a rate of 70 per cent. The Metropolitan estimates that on this venture it returned the money invested in the examinations and made a profit of 200 per cent in five years. Naturally, an insurance company makes money when less than half of the expected mortality occurs in any group, for the whole business is scientifically figured out according to actual experience. This particular group represented mostly \$5,000 policy holders, that is, persons of fairly good economic status, with perhaps more than average intelligence, as they realized the benefits of health examinations. While they may have been a group slightly superior to the average, the data are, nevertheless, extremely significant, as showing the personal advantages of these health inventories. Another fact brought out was that unless the examinations were regularly repeated, the beneficial effect wore off in about five years.

Because the desirability of these health examinations is universally conceded, and because practically every official and voluntary health agency in the country has advocated them and still does so, the National Health Council voted early in 1922 to hold three health days. These were to have occurred in December and an attempt was to have been made to induce every one in the country to go to his or her physician on one of these days and be examined. On the advice of leaders in the medical profession, who believed that the doctors were not quite ready for such an intensive drive, this proposition was postponed. Instead, a whole year was determined upon as a better period with such concentrated campaign in any state as local conditions might warrant. The proposal was presented at the convention of the secretaries of state medical societies, who gave it their endorsement. The medical profession of the country has never yet failed to discharge a humanitarian responsibility which has been asked of it and it will do so in this instance.

With the slogan, "Have a Health Examination on Your Birthday" this campaign of the National Health Council began, appropriately enough, on the nation's birthday, July 4, 1923, and will last until July 4, 1924. The goal during this year is ten million examinations. The Conference of State and Provincial Health Authorities of North America has endorsed the movement and the National Health Council has invited each state health officer to take the initiative in forming state health examination committees. The response to this invitation has been most gratifying. The functions of these committees are to stimulate the formation of local committees and see that plenty of publicity is obtained. For several weeks before the campaign started the Council sent about a dozen news releases to two thousand of the leading newspapers of the country, who used practically all of them and furthermore, thought so well of the idea that many of them wrote unsolicited editorials favoring it. The United States Public Health Service also sent out from Washington a news release on the campaign which was very extensively used and even appeared in newspapers in London, England.

The National Health Council has

also developed publicity material, consisting of an eight page pamphlet for popular distribution; two posters, one in colors and one in black and white; a set of thirty colored lantern slides with a lecture outline, and a motion picture. The co-operation of the medical profession, which, naturally, is essential, having been secured, a committee of the American Medical Association has prepared standard forms for the use of physicians. A technical article on the subject by Dr. Haven Emerson has been reprinted from the *Journal of the American Medical Association*. An excellent popular article by the same author appeared in *Hygiea*. The National Health Library has prepared for the Council a bibliography of the principle articles on the subject. All of the publicity material is for sale at cost by the National Health Council, except the examination forms, which are obtainable at cost directly from the American Medical Association. The motion picture will be distributed for transportation cost only through the co-operation of the Metropolitan Life Insurance Company.

The National Health Council believes in practising what it preaches. It has, therefore, made arrangements for all members of the staffs of its constituent organizations whose headquarters are at 370 Seventh Avenue, New York City, to receive health examinations, either at the Cornell Clinic or at the health center of the Women's Foundation for Health, both in New York City. This is a custom which has been followed for a number of years. During the few months of this year's arrangement more than a third of the personnel of three hundred has been examined. The employees of the New York State Department of Health have been regularly examined since 1922, as have those of many other health departments.

If the endorsement and approval of every leading sanitarian in the country and of every official and voluntary health agency can make a campaign successful, this one ought to be. If public approbation, as expressed through the public press, and by individuals, indicates the support of the people, it is certainly there. It looks as if the human machine was going to get a trifle more consideration during this health examination year than ever before. The greatest compliment that can be paid to any mechanism is to say that it is almost human. The human machine is the most intricate, the most delicate, the best constructed, the most valuable and the one most

worthy of consideration of them all. Whether one goes on the birthday or not for a health examination, it is a present which all owe to themselves. It is the Gift of Life, itself.

Summary

(1) A health examination is a medical appraisal of an individual to ascertain physical impairments and faulty habits, with a view to correcting them.

(2) Health examinations are necessary in the public health movement because the emphasis is changing more and more away from environmental control to the inculcation in the public of personal hygiene.

(3) The experience from health examinations shows that at least three out of four persons have physical defects.

(4) The results of health examinations are to lengthen and enrich the life of the person examined.

(5) The National Health Council has inaugurated a National campaign to induce at least ten million people to have health examinations, between July 4, 1923 and July 4, 1924.

Diphtheria Compensable

Diphtheria as a compensable disease was passed upon by the Supreme Court of Pennsylvania, January 3, 1923. It seems that prior to his injuries the deceased was in good health. January 21, 1920, he fell from one of the defendant's buildings to the ground. He was taken at once to a hospital severely bruised in various parts of his body, particularly his back. It was found that "the transverse processes of three lumbar vertebrae were fractured, accompanied by partial paralysis of the right side, some internal injuries, and a condition of shock." On the tenth day after his admission to the hospital, McCoy, the injured employee, developed some trouble in his chest which seemed to indicate pneumonia. This cleared up, but an examination of his throat revealed the presence of Streptococci, and he was given a serum treatment. On the morning of his death he coughed up some casts, and later the trachea was opened and a quantity of membrane removed. A post-mortem examination showed the existence of diphtheria germs, and it was agreed by physicians and surgeons in attendance that death was caused by diphtheria.

The Board found diphtheria the cause of death and allowed compensation because the "vital resistance was so lowered (by the injuries re-

ceived) that he could not resist the infection by diphtheria bacilli, which attacked him after the injuries were sustained," . . . (adding) "the developing of the diphtheria and its final result was under the circumstances a natural resultant effect of the injuries. The lower court reversed the award of the board because the witnesses did not testify that "taking into consideration all the attending data, it was their professional opinion that result in question most probably came from the cause alleged" and was upheld by the Supreme Court.—*McCoy vs. Jones and Laughlin Steel Company*, 119 Atl. 484.

An Adverse Decision

An injured employee contracted gonorrhea after the accident and the resulting gonorrheal arthritis postponed his recovery many months. The Supreme Court of Illinois in passing upon the situation February 21, 1923, decided that the man could not recover under the Compensation Act for any disability caused by the disease, but only for such disability as was solely caused by an accident arising out of his employment.

"The authorities in this country . . . are to the effect that an employee can only recover for a disability that is caused entirely by the accident which he received in his employment, and that the employer is not responsible for any part of a disability that has been occasioned by another independent agency that has intervened after the accident occurred."—*Bunce Bros. Coal Co. v. Industrial Commission* 138 N.E. 189.

Medical examination for food handlers in Newark, N. J., includes only the most elementary steps to determine the presence of ordinary infections. Among 11,851 examinations made during 1920 to 1922 only thirty-seven cases of venereal disease were discovered, states the health commissioner of Newark in a recent issue of the *American Journal of Public Health*.

Jewish Population Statistics

According to figures recently given out by the Bureau of Jewish Social Research, there are more Jews living in the United States than in any other country. About 3,600,000 are living here; Poland has nearly 3,500,000 Jews, and Russia shelters 3,130,000. New York City is the Jewish city of the world.

The One Best Way for Executives

(Continued from page 613)

many years, and has already been described in writing.

High Cost of Fatigue

You will find little general recognition of the high cost of unnecessary fatigue, which has been conceded by experts to amount to more than twenty cents per day per worker. You should ever bear in mind that the costs from unnecessary fatigue become a part of the high cost of living and are borne by the entire public.

It is expected that you will use your influence in the guidance of national thought and attitude toward the scientific method in business and in industry.

You will find that the tools used in the industries are of all kinds from the best to the worst, and that the two extremes may be found everywhere side by side.

There is no general knowledge even in the manual training schools of the waste that comes from acquiring automaticity with inferior tools and from dividing one's practice and the resulting skill between two or more different kinds of tools for accomplishing the same purpose.

Everywhere any kind of tools are thought to be good enough for an apprentice or other beginner to use during his learning period. There is almost no knowledge even among executives, of habit interference resulting from excess variety of tools and methods. There is almost no recognition of the fact that automaticity is the greatest free asset of the working man and all others who have time for sale; and even a great dental society recently had for its convention program the motto, "Learn All Ways."

You will find it by no means unusual to enable workers and clerks to produce from three to five times the output when they are furnished the one best of each kind of necessary tools and standard conditions.

You will find that one of the chief causes of low outputs per worker is the failure of executives to furnish workers with the right materials, in the right conditions, at the right time and in the right quantity. The same condition prevails in causing low records of sales in our great retail stores.

For those who do not realize what these astounding totals amount to, let us compare them with something that

all people admit is a colossal sum, namely, the Allies' debts to the United States of a eleven billion dollars, which is only one hundred dollars per person living in this country. The preventable waste that you will find is much more than one hundred dollars per person per year, when figured in goods and opportunities for the enjoyment of leisure.

A large part of the working people believe limit of output causes more employment. It is your duty to teach the benefits of maximum outputs per unit of time per person. Conditions are so bad that they would be reformed at once if it were not for the fact that any organization is fairly safe if it is as efficient as its competitors.

In fact, conditions generally are so bad today among competitors, that every banker knows that with an expert in charge of sales, an organization may be fairly successful, even though the manufacturing department is not guided with anything like equal ability. The same thing is true when the conditions are reversed, and the production department is handled with great skill, and the sales department is handled with less ability.

The great financial and industrial organizations are usually successful because of greater efficiency, and after awhile, if they lack the spur of competition or a definite program for improvement, they finally fall into obsolete ways.

This is not, however, to convey the impression that *all* organizations are to be regarded as inefficient or that all workers have inferior methods. Such is far from the case, but my own work of consultant in problems of management over a period of twenty-seven years impresses me chiefly with the characteristic unevenness in the efficient working of the average organization.

Business Needs Leaders

I am also deeply impressed with the inexcusable inefficiency of workers everywhere, and this must be held as due to the fact that employers in general have made no concerted and systematic attempt to make available the details of the best and least fatiguing method extant to all who wish to learn or teach it. The employers, too, are the losers as the same improvement of method would increase the

output and reduce the energy and money expenditure.

Much talk is abroad of the "foolish customs and practices of the working people," but it is to be noted that they have had no schooling whatever in economics, they have not related their own activities to the problems of the day. They honestly believe that executives only await a suitable opportunity to take unfair advantage of them. They are nevertheless quite interested "to do the right thing for general prosperity," but need to be shown the way. Their principal shortcomings are due to the lack of leadership and to the absence of instruction. If you are tempted to blame them for the bad leadership to which they are often subject, a fair comparison of your own political leaders will perhaps engender more patience with them. A similar undesirable educational status marks the English worker, hence the recent intelligent effort to furnish training in the fundamentals of economics in the workers' schools.

There is unlimited opportunity for service in America along these lines. And such instruction is not needed by working people alone. It is needed all along the line. Some of our most respected men and women of affairs, all of whom vote, have next to no conception of or interest in even the most elementary principles of economics.

Mere Repetition, Not Skill

Many people are thoughtlessly inclined to assume that special equipment along a given line is all that is needed in a worker. It seems to them that the bricklayer who knows the mechanics of his work, or the typist who has been able to hold down her job for twenty years, or the surgeon who industriously operates in the same hospital year after year can therefore be accredited with skill in their several lines of endeavor.

But remember, no two workers and no two teachers of workers in any trade or profession do their work precisely alike. Therefore they are probably all wrong but one. Not theory alone favors economy of effort. Long experience and painstaking, leisurely examination of micromotion study of the best possible demonstrations have demonstrated as final the principles which underlie the development of the

standard method in any given occupation.

Even the pickers of berries, working at a trade perhaps as old as the berries themselves, have shown, under the most careful and painstaking analysis of their behavior, no indications whatever of having inherited any instinct for picking any kind of berries in the one best way. No two farmers and no two deans of agricultural colleges agree upon the one best way as to methods and motions of the simplest repetitive processes upon the farm.

There is the wide possible range of improvement in all kinds of work, and for executives who desire to participate in guiding trends of progress. The list could be extended indefinitely. Our schools and colleges are in the same predicament. There are exceedingly few college presidents today who will not admit that the methods used in our schools are bad. Each will tell you that he is hindered because he is surrounded by traditions, customs, and the mental inertia of his trustees, the majority of whom are so pleased to be on the board, that progress by the fumbblings of slow evolution seems to be the only possible way. Two college presidents have expressed themselves openly to me on this subject within six months. Talk to the head teachers of the high and grammar schools and you will find the same conditions plus the further handicap of the necessity of fitting for the obsolete methods in the colleges, together with the added fear of speaking the facts.

You will find that much trouble comes from lack of measurement. I could give you names and places where actual measurement of school affairs is being done at the present time, and fathering the facts is causing some trouble for the measurers. The new science of business management is a problem in teaching, and if you make your decisions as a result of measurement you will be nearest right the largest percentage of times.

The world needs you to emphasize and give prestige to such axiomatic truths as surround the finding and presentation of the one best way to do work, as demonstrated by the best demonstrator possible, operating under motion study experts.

You will not be called upon to fumble, invent, perfect and learn how to use efficiently the units, methods, and devices for obtaining the one best way to do work, for the laborious studies of the pioneers of efficiency standards have already perfected

methods and devised unit measurements.

Your generation is lucky. You appear upon the scene in the world's history when sufficient of the units, methods and devices for recording, analyzing, measuring, standardizing and synthesizing elements of the one best way for executives to do work have been developed ready for you to use.

Find Facts And Know Them

You have been taught how to find facts, how to know facts and how to use facts. The scientific method of attack is now at hand and in your possession. The detailed technic of finding and using the one best way is now available, and the training which you have had prepares you exceptionally well for such work. It is necessary only to point out to you the needs for your endeavor.

The great opportunity for precision study that you have enjoyed has not been given for your benefit alone. You have now a religious duty as expressed by the greatest law for conduct and also, happily, the greatest law for management, namely the golden rule, and the greatest joy in the long run will come to you in the joy of achievement in service to your fellow man. You must use these opportunities to standardize human service.

You have had the best opportunities, far, far beyond the average. The "average methods" have never led to maximum progress. The "average man" has never led civilization anywhere. You can lead because your opinions will be respected, they will be based upon cold-blooded measurement.

The super-method of the super-leader and super-executive will bring us in the shortest time to the one best way in all things—that all may have more of the durable satisfactions of life. It is your duty as executives, to put that idea into the minds of all men according to their capacities.

All problems relating to the methods for altering the conditions cited here have already been solved. The results can be seen in successful daily use. It is expected that you will be satisfied with nothing less than the dissemination and application of the one best way for executives derived from measured facts.

John P. Harris, chemical engineer specializing on edible oils and packing house work, has been appointed director of the Bureau of Practical Research of the Institute of American Meat Packers.

Distinguished Industrial Hygienist Visits America

Sir Thomas Oliver, the distinguished British occupational disease expert, will visit the United States during September and October. Sir Thomas contemplates a rather extended trip, as far west as Chicago and as far south as New Orleans, chiefly for the purpose of visiting representative industrial establishments suggestive of the progress which has been made in industrial hygiene and employee's welfare work since 1912, when he made a similar tour of inspection, limited, however, to a more restricted area. His study will include oil refineries, felt hat-making, potteries, printing and electrotyping establishments, industries concerned in the manufacture and handling of asbestos, tobacco, cotton, iron and steel, sugar, white lead, limestone, motor cars, rubber, paper, wool, and possible coal and slate. The itinerary of the trip is in charge of Dr. Frederick L. Hoffman, consulting statistician of the Prudential Insurance Company of America.

Disability from Fall

In the employ of the Hardware Company an employee was running a truck load of heavy hardware across the floor March, 1918. Mr. Parkinson, who was pulling, fell down because a stake on the truck gave away. He arose without assistance and went on with his usual duties. He lost no time and employed no doctor. He left to take other work with a railroad company, but contracted "flu" and was seriously ill. He returned to the railway company and May 20, 1919, was operated for gall bladder trouble. He returned to work but was again operated January 16, 1920. It was found that he had developed Pott's disease and was disabled for further labor. The question is raised as to whether the disability is chargeable to the fall. It was pointed out and agreed since "there is no competent or disinterested evidence in the record indicating imminent symptoms" during the nine months following the fall, the claim necessarily fails. The case involved "a disputed question of medical fact as to whether the alleged injury was the cause of the Pott's disease and the resulting disability, or whether the Pott's disease resulted from some other cause. Inasmuch as there was ample evidence to support the decision of the commissioner, the finding was upheld.—*Parkinson v. Brown Camp Hardware Company*, 192 N.W. 420.

Health in Girls Continuation School

(Continued from page 604)

attractive and in a quiet part of the building. There should be provided an examining table, scales, well supplied first aid cabinet, examining gowns, mirrors for corrective work, a desk and suitable charts for instruction. If a separate rest room can not be provided, the examining room should be large enough to permit the screening of one side for a couch, so that girls taken ill at school may receive immediate first aid treatment.

According to the proposed scheme of health education each girl in the school receives at least one complete examination each year. This is given as soon as possible after her admission to the school. If there are indications for other minor examinations during the year, these are provided.

When the girl is ready to leave the school, she is examined by nurse or doctor for general appearance and cleanliness. All of her follow-up cards are checked and her diploma is not granted unless she has a passing grade in health and cleanliness.

By a close follow-up system, each girl is so frequently checked during the year, there can be little possibility of her failing to measure up to these final requirements.

Hygiene of instruction includes a consideration of the entire school environment. Our problem is not alone what shall we teach these girls, but also, how shall it be taught in the most telling manner and under the most attractive and hygienic conditions.

The girls come under the school influence but a few hours each week. These hours must be made to count. From the minute the girl enters the buildings she should be made to feel that the school has been created for her. She should find here every necessary comfort and as many luxuries as the school can provide. In many cases the hours spent in the classroom are the only relaxation periods in a long week made up of days spent bending over noisy, ceaseless machines, or spent standing at tables

monotonously matching cigars or mechanically pasting labels on paint cans.

Instruction In Hygiene

In the school room the tired factory girl should be made comfortable, and as happy as may be.

Instruction in hygiene forms an important part of the health program. The course of study should be made to fit the needs of these particular

Classroom instruction should be given: (1) by the class room teacher in connection with the regular class room work; (2) by doctors as he visits the various rooms from time to time. Definite cases discussed bring greater results than general talks or lectures; (3) by the nurse as she makes daily inspection or goes from room to room checking the follow-up work; (4) by visitors or invited speakers, who may be interested in health subjects.

Special interest could be aroused in these talks if the girls could be assembled for them.

Instruction in Physical Training should include setting-up drills, breathing exercises, general drill in posture for all girls, special individual work for girls with marked postural defects, marching to music, games, and folk dancing.

Without explanation, this may seem an elaborate program of physical exercises, but all these lines may be followed by devoting only a few minutes each day to this work.

In the summary of his report, Dr. Mitchell indicates as follows the lines along which there should be more activity in order to provide properly for the health of these children:

(1) Demonstrate how the problem can be administered efficiently and economically.

(2) Study the environment of the employed adolescents to understand the relative importance of factors influencing health.

(3) Study course of various physical handicaps under conditions of employment in order to establish better standards for health protection.

(4) Devise methods of teaching hygiene for the industrial and mercantile worker.

If the course of procedure suggested were followed, it is believed provision would be made for increased activity along the lines which Dr. Mitchell suggests.

The plan requires the services of a physician for but three half days each week; of a full time nurse, and of a teacher of physical training for one hour each week. We believe this would provide for the "efficient and economical administration of the problem."

Educational and Physical Standards

ALL except eighteen states make some legal provision regarding a child's physical ability to go to work, but only twenty-two states make such examination mandatory. Nine states still permit children between fourteen and sixteen years of age to work ten or eleven hours a day. Physical examination at regular intervals is the exception, not the rule. Compulsory part-time school attendance is called for in twenty-six states, but only twenty of these require schools to be established under specified conditions. Health supervision, chiefly to be applied through continuation schools, presents the special problems outlined in the Newark survey.

girls. Such a course of study can be formulated only by those who know and have come to appreciate these needs through intimate, sympathetic association with these girls.

All the workers in the school should cooperate with the doctor in outlining the health program. The subject matter should be varied and should be related directly to the interests of these particular girls. The introduction of practical work into this school will afford abundant and valuable opportunity for the correlation of health work with cookery, dress making, housekeeping, etc.

No definite periods during the day need be devoted to so-called hygiene. Health should be taught throughout the day; every opportunity should be utilized.

KOTEX

Another advantage to women

Few new ideas have ever scored such quick and sound success as Kotex. Women everywhere approve this wonderful sanitary pad. Only three years after its introduction, Kotex is today an important part of the American woman's toilette.

Kotex forms a new habit from the very first box. It solves a laundry problem. It meets the most exacting needs. It is easy to dispose of and cheap enough to throw away by following simple directions found in each box. It is comfortable, convenient and *instantly available*.

Kotex is made from fine gauze and Cellucotton, which is said by scientists to be the most perfect absorbent material—much more absorbent than ordinary cotton. Kotex is far superior to old fashioned make-shifts.

The first box of Kotex brings a new convenience, a new comfort, a new economy.

Sold everywhere in good stores that serve women. One need only say Kotex—

Ask for them by name

Regular Size, 12 for 65c
Hospital Size, 6 for 45c
(Additional thickness)

Kotex cabinets are now being distributed in women's rest rooms everywhere — hotels, office buildings, restaurants, theatres, and other places — from which may be obtained one Kotex with two safety pins, in plain wrapper, for 10 cents.

INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX

Am I Physically Fit to Teach?

(Continued from page 586)

present at each meeting. Where it is necessary, the school nurse or nutrition worker visits the home.

Tuberculous Children

Included in the twenty classes are those conducted at the two schools for tuberculous children. Here it is possible to carry on an intensive program that has developed gratifying results. During the past semester twelve cases of active tuberculosis have been pronounced arrested as compared with eight cases for the entire school year previous to the introduction of this special work. And the average gain in weight at present is 8.9 pounds per child as compared with 2.7 pounds. During the summer the nutrition classes are continued at the Children's Day Camp where these little folks spend their vacation. And the nutrition worker keeps in close contact with the homes, in an endeavor to improve general conditions.

Other extensions of this city-wide nutrition campaign are:

(1) The mid-morning milk and graham cracker lunch service in 86 school buildings. The average daily consumption is 15,695 half pints of milk with from 2 to 4 graham crackers with each bottle of milk. In a large number of the schools, the teachers take the entire responsibility of this service to children. In other schools members of the Parent-Teachers Association are in charge. The milk, a straw, and two graham crackers are sold for four or five cents. The children are encouraged to spend their pennies for this wholesome lunch instead of dill pickles or lollipops. The quality of milk selected is determined by the rating of the dairy. The school principals were asked to place their names on the mailing list of the monthly Milk Rating Bulletin issued by the Board of Health, and to select the milk having the highest rating. This has a tendency further to improve the quality of all milk and in turn benefit the general public.

(2) The weighing and measuring of 18,972 school children who play the red, white and blue weight card game and to whom a four page folder was

distributed containing a daily health program and information regarding the importance of correcting physical defects.

(3) The "Health Jingles" attractively illustrated are distributed annually to all third grade pupils, and to all fourth grade pupils the health rules of the local Tuberculosis Association. At the suggestion of the superintendent these publications are used as subject matter by the teacher before the children take them home.

(4) A syllabus on "Health Training and Instruction" was written by the director of physical training for the teachers of the elementary and

junior or thrashed me." Now instead of "thrashing" the nervous, irritable underweight child, he receives a physical examination, is told how to get well, and is taught daily how to keep well. The results are infinitely better.

The Best Modern School

Today the best schools are placing proper emphasis on health. Physicians and nurses are keeping a watchful eye upon the pupil through regular medical inspection, and a record of physical progress is filed along with the record of progress in study.

The majority of parents can afford to pay for medical advice regarding the care of their children and appreciate the value of possessing the best scientific information for maintaining health. In many cases, however, this service can not be paid for except in emergency. In other cases parents do not realize the importance of preventive practice. It is that part of malnutrition and illness due to ignorance or economics that is finding solution in the clinical examinations and the widely extended teachings of good hygiene now rapidly becoming a part of the curriculum of all modern public school systems. The less progressive communities re-

sist this extension of medical and health supervision of their children by the school physician, nurse and nutrition workers, believing this duty lies entirely within the province of the home.

However, in the very creation of free schools and compulsory education we have acknowledged the fact that we can not entirely rely upon the initiative of the parents. Who then can question that the physical development of the child is not of equal importance with his mental development?

The waste of skim milk in this country is a crime. The Department of Agriculture estimates that the amount of skim milk represents annually a protein value of 913,000,000 pounds, approximately equivalent to eight billion pounds of beef, which is said to be nearly equal to the annual consumption of beef in this country.

Miner Normal School student teachers, seriously underweight, ready to return to their studies after taking their rest periods on the roof of the school.

junior high schools of the District of Columbia.

(5) Children 10 per cent or more underweight for height are excluded from strenuous athletics. This new ruling was inaugurated last year after the physical training director's attention was called to the various reports of the nutrition teachers showing these seriously underweight children lost weight consistently while participating in the spring athletics. Formerly it was customary to exclude only the pupils who were below the 71 per cent requirement in their studies. A minimum standard of physical fitness is now recognized to be of equal importance.

A prominent educator recently said "When I went to school the teachers were supposed to train my mind, but they did not know what to do with my body, it wanted to wriggle and twist about and so they stood me in a cor-

Agencies in 288 other cities

You Will Enjoy Walking in these Comfortable Shoes

LATE afternoon—footsore shoppers turn to glance with admiration and envy. Who could look fresher and lovelier than a fashionably dressed woman swinging along in shoes as light and flexible as her step? All the vigor and grace of youth are in her carriage.

Comfortable Cantilever Shoes do away with tiring, shoe-bound steps. Flexible arches act in agreeable harmony with every demand of your supple foot arches, as the rigid arches of ordinary shoes cannot. This flexibility allows free play, giving to all the foot muscles the normal exercise that strengthens them sufficiently to hold the 26 small bones of the foot in their proper arched positions.

Cantilevers support, too. The snug-fitting, flexible arches curve up when

you lace the shoe, to support the arch of the foot, gently and naturally, on the inner and weaker side. Your feet are enabled to carry properly the weight of the body without strain or restriction of the foot muscles. In trimly shaped vamps, your toes can straighten out in comfort. Natural lines and moderate heels afford a firmer purchase on the ground and the poise and grace which come from that.

Walking is so often a dreaded effort that tires the feet and frets the face. In Cantilever Shoes, it's a joy, an invigorating exercise that stimulates the circulation and brings a healthy color to the cheeks, such as you see on those smart American women who spend much of their time out-of-doors at the country club.

Except in New York and Chicago, only one store in each town is selected to sell Cantilever Shoes. If no dealer in this list is near you, write the manufacturers, Morse & Burt Co., 15 Carlton Avenue, Brooklyn, N. Y., for the name and address of a nearby dealer and a new booklet on the subject of feet and comfort.

Endorsed by women's Colleges, Women's Clubs, Public Health Authorities, Physicians, Osteopaths, Directors of Physical Education, Editors, Stage Celebrities and prominent women everywhere.

Cantilever Shoe

ILETIN INSULIN, LILLY

The active principle derived from the islet tissue of the pancreas of animals, prepared in aqueous solution for use in the treatment of diabetes mellitus.

This product was discovered and developed in the University of Toronto and is made on a large scale manufacturing basis, under the authority of that institution, by Eli Lilly and Company.

Physicians who contemplate using Iletin should study carefully the information now available, particularly that relating to the adjustment of unitage to diet and the prevention of accident due to overdose. It is advisable that patients be given a preliminary treatment in a hospital or an institution in which adequate dietetic and laboratory supervision is available.

LARGE SUPPLIES AVAILABLE AT VERY MODERATE PRICES

Present stocks of Iletin are in excess of national current use and our facilities for production will meet any conceivable demand.

At present Iletin is not carried in stock by the drug trade. It will be sent directly from Indianapolis to physicians and hospitals on orders placed through druggists. These orders will be invoiced to the druggists.

Iletin is supplied only in 5 c.c. ampoule vials. Order as:

H-10 (50 units) containing 10 units in each c. c. \$1.75
H-20 (100 units) containing 20 units in each c. c. 3.00

[F.O.B., Indianapolis]

AVERAGE DAILY COST TO PATIENT

In reply to inquiries and mis-statements concerning the cost of treatment, one of the largest clinics using Iletin reports that the average consumption per patient is ten to twelve units per day, costing thirty to forty cents. It is our policy to keep the price moderate and to give users of Iletin a share in the economies that may result in the future in increased production due to a larger consumption.

Pamphlets on Iletin and order blanks will be sent physicians on request.

ELI LILLY AND COMPANY
INDIANAPOLIS, INDIANA

The Market As a Service Institution

(Continued from page 588)

section on either end, four inches in depth, allows the fish to be displayed on crushed ice and protected from the inquisitive finger of the purchaser. Two large center storage sections serve for temporary storage of a reserve supply of fish and allow for immediate replenishment of the display supply. These sections are insulated with cork and a drain connects with all sections to carry off the waste. The cost of the stand was about one thousand dollars.

A poultry display stand, in which the dressed poultry under a glass protector can be seen by the purchaser to advantage and still be kept in a sanitary condition, which has been installed at a cost of about one thousand two hundred dollars meets the most critical inspection. A new stand for fruits and vegetables has been installed for about \$650, and several bakery stands are under construction. Improved, refrigerated meat stands are still under study.

These new stands replace the oldest and most undesirable stands in the market. Rents are increased 20 per cent so that the stands will pay for themselves within four or five years. There is a great demand for them, and the superintendent has many requests from standholders that their stands be rebuilt in accordance with most modern designs. Some of them have not hesitated to bring pressure to bear to secure the new stalls, showing the appreciation of improvement and the advertising value of sanitation. These improve-

An especially designed stand for selling dressed poultry. Center Market, Washington, D. C.

A model distributing market for fish at Center Market, Washington, D. C., which is a part of the only meat market in the country employing the exclusive services of a meat inspector on full time. Improved refrigerated meat stands are still under study.

ments will be made as fast as earnings warrant, and according to prearranged plans of development. Specifications for these stands are available to other public or to private markets.

Mr. Kitchen's administration of Center Market during this year has demonstrated that increased efficiency in operating a market can so increase revenues that additional funds are made available for increased sanitation. Not one but many changes in management have brought in or increased revenues for the property. Some have meant only a few dollars increase, others have meant an increase of many hundreds of dollars.

Center Market is probably more effective as a demonstration than a new market would be. There should be no difficulty in maintaining high-class conditions in a new plant, but to renovate an old one and make and keep it wholesome and sanitary is quite another matter. That is the problem that at one time or another confronts the large majority of American cities.

"Sanitation is a good business asset for any market" says Mr. Kitchen. "The patrons appreciate it and with it they are willing to recommend the market to their friends, when without it they wouldn't even if they continued to trade there themselves. It provides one of the best bases for advertising. It increases the standholders' pride in their business and the town's pride in the market as a civic institution."

Fresh Air Outings in Child Care

(Continued from page 592)

pational therapy and education? Is the aim to meet the needs of a child, or to offset the failures and shortcomings of organized society and familiar weaknesses?

The answers to these questions will help to define the objectives of fresh air agencies as a factor in child care. Similarly, it will aid in determining whether or not a doctor or nurse, or both, should be constantly in attendance at places where children are to receive this supplemental physical advantage.

There is definite data available to indicate what can be accomplished through fresh air classes, health centers, nutrition classes, infant welfare stations, mental hygiene clinics, and similar medico-social agencies, under the ordinary conditions of city life. Hence, from a distinctly medical standpoint, one may properly suggest the importance of careful inquiry into the purposes, administration, and end results of fresh air outings.

Statistics thoroughly demonstrate the superior health of children in the city over those in rural sections, indicating that fresh air is by no means the single dominant element to be considered from the health standpoint, omitting all matters of sentiment, interest in recreation, or the making of purely social adjustments.

The death rate of New York City for January, 1923, was 13.1 per thousand, while for the rest of the state it was 20.0. The infant mortality for the same month in cities and other incorporated places having a population of 2,500 or more, at the 1920 census, was 106, and in the rural districts it was 95, while in New York City it achieved the excellent figures of 71.

While these figures are for a single month in 1923, they are fairly representative of the comparative statistics during all seasons of the year. It may be fairly said that the actual part played by fresh air agencies in bringing about the reduction in infant and child mortality in New York City has been the least effective factor, if one omits sanatorium care and convales-

cent homes, but lays stress only on the assistance given by means of fresh air outings. It must be remembered that when the movement towards fresh air outings was first begun, there was a general lack of the more modernized educational approach to the problems of child welfare. As is usually the case, an institution once founded tends to continue until there is a check in the program by reason of an overwhelming proof of its relative place in communal-social organization.

The dinner call, Children's Summer Home, New York Children's Aid Society.

The bulk of the organized fresh air work for children of the school age possesses questionable warrant on the basis of health requirements. The lowest mortality rate and smallest number of deaths occur among children between five and fourteen years of age, as compared with other age groupings. The function during the school period is in connection with disease states and their sequelae, or the attack upon incipient maladies as determined by protective medical inspection or examination.

The Preventive Standpoint

The requirements for outings before the age of five years are probably greatest from the preventive standpoint, providing the period of stay is sufficiently long to possess prophylactic value or bring about a restoration through an adequately supervised convalescence.

The importance for particular attention to the physical needs of children between the ages of five and six may be stressed, as it is desirable to secure for them the highest health potentials before undergoing the inherent hazards of schooling under existent conditions. Another special age period arises during the first two

years of life when vital energies are sorely strained by nutritional difficulties and a lack of properly ventilated homes. From the point of view of service, much greater attention is required to the help that may be given to children who present problems in behavior. As a medical procedure, it may be essential to secure placement for various periods of time in open air homes and camps, foster homes or institutions, now designated as convalescent homes. My experience with

this group has revealed the inadequacies of our plans for meeting their needs. At the present time this phase of the problem is serious in connection with the after-care of children who have conduct disorders or alterations of personality, due to encephalitis. Our program has not taken sufficient cognizance of the readjustments required for hysterics, pseudo-epileptics, adolescents with emotional

crises, and the group that is undergoing the complicated strain of neuroses and potential psychoses.

Should there not be a further consideration of the preventive values of fresh air care in terms of all subnormals, mental and moral, as well as the purely physical substandard children? The interrelation of all elements of a child's nature has a distinct bearing on each factor contributing to future social and economic efficiency. It becomes necessary to broaden our outlook beyond tuberculosis, cardiac disease, infantile paralysis and post surgical restorations. The field of service should be mapped out in the light of the medical benefits that are to be secured for raising the standards of communal health and welfare.

I do not wish to be misunderstood. Fresh air outings have been of considerable value, but I am now speaking particularly from the medical point of view and in terms of preventive and therapeutic end results. I believe that their complete potentials have not been developed, by reason of a failure to appreciate their possible contribution to the complete physical life of children. I have noth-

Experience is the Best Teacher

RIGHT! Whether the experience be yours or that of others, the profitable lesson is there to learn and follow.

Now let us see what experience teaches regarding Coffee.

Hektoen and LeCount, probably two of the greatest pathologists this country has produced, have shown conclusively that the continual use of caffeine in the small doses usually found in Coffee, *produces no lesions whatsoever* in any tissues of the body. Is there any equivocation there?

Again, Hollingworth has definitely shown that caffeine enables a person to do more mental work in a given time than he is capable of doing without it; and—*here's the point*—the increased work is *not* followed by depression or exhaustion. Positive, isn't it?

In the face of these authorities—and we could quote many more—is there any wonder that the thinking physician

hesitates before taking from the breakfast table the patient's accustomed, cheering cup of Coffee?

Only after the *clinical findings* indicate the necessity, or even the possible desirability of such action, does the physician of to-day strike Coffee from the dietary. Experience teaches him that it is wise to keep the patient's diet as near normal as possible; that it is as unwise as it is generally unnecessary to rule out Coffee. Experience teaches him that he can turn Coffee, the favorite morning beverage of most Americans, to good account, because it is a mild but reliable cardiac stimulant, an aid in constipation, a renal tonic, and a first aid to unresponsive appetites.

Think of these facts before unreservedly banning Coffee. Let the diagnostic findings of *each particular case* dictate your action.

ing but words of appreciation for the social and recreational service which has been provided and which admittedly does contribute to raising the general levels of physical comfort and happiness of childhood, particularly during the long heated summer season.

Is it not important, however, to consider the fresh air program in terms of a three hundred and sixty-five day year and to organize all existent agencies in such a manner as to provide for a better distribution of service throughout all the months, rather than to allow the bulk of the enthusiasm, as well as the facilities, to be centered about the vacation period? Outings in January are no less useful than in July or August, from the viewpoint of prophylaxis or therapeutics, if health is the aim.

Why Only in Summer?

The fresh air outings are not to be regarded as a plan for summer care of children, but should be interpreted as a valuable supplemental aid throughout the year, for the purpose of raising the health standards of the community. There should be large and small institutions and camps for the general management of problems arising in connection with lowered physical vitality, not related to specific maladies. Similarly, there should be places which will receive children for indefinite periods of time, in order to care for a considerable group of conditions of non-contagious nature, requiring little medical oversight or nursing care. Other types for more or less permanent care, as preventoria or sanatoria, are necessary for the care of the tuberculous, the cardiopaths, the rheumatics, choreics, and those recuperating from surgical procedures or mental imbalances, wherein medical supervision and nursing care are requisite. Further, there should be a development of fresh air homes that accept one, two, or three children, for a larger variety of conditions than are now cared for by the Speedwell's system. In all, however, I firmly believe that the period of stay should be determined by the physical needs of the child, rather than pre-determined by a definite, fixed policy, arranged on the basis of giving a limited amount of care to the largest number of children.

This admittedly is a purely medical point of view, even though I am thoroughly conscious of the point of view of organizations operating fresh air homes and of social workers. I am thinking and talking in terms of the maximum benefits to the largest num-

ber of children actually meriting this special care, rather than of limited benefits to a still larger group of children, for whom it is not imperative. I am speaking for the greatest service to the community, as preferable to the small returns that result from the large, wholesale fresh air outings. Quality of service should take precedence over quantity, in measuring the medical values of fresh air outings and convalescent care.

Aid to European Medical Scientists

"We need food not only for our bodies but for our minds," wrote a Russian medical professor in acknowledging the receipt of periodicals and books provided by the Rockefeller Foundation. The Foundation has left to other organizations the task of emergency relief and has concentrated efforts upon helping to maintain the continuity of scientific work by filling gaps in medical libraries, contributing apparatus and supplies to laboratories, supplementing the stipends of productive research men, granting fellowships for foreign study, and inviting commissions to make international visits.

"During 1922, journals to the number of 1,323 subscriptions were sent to 216 medical libraries in twelve different countries. In a number of places committees of scientists arranged for the abstracting and circulating of periodicals and thus utilized them to the utmost.

"The wearing-out of apparatus and the depletion of current supplies in scientific laboratories were inevitable results of the war. The medical schools of Vienna, Gratz, Budapest, Innsbruck, and Prague were among the first to suffer acutely. To these the Foundation made grants. The scope of emergency laboratory aid was later extended to include German and Polish laboratories.

"Serious as were the problems of literature, equipment, and supplies, the question of personnel was absolutely vital. It was feared that the continuity of scientific progress might be interrupted, because young men either would be unable to go on with their studies or could not be trained to the oldtime efficiency. To assist the Pasteur Institute of Paris to recruit and educate research assistants the Rockefeller Foundation pledged in 1921 the sum of \$75,000 to be paid in three installments during 1921, 1922, and 1923. Fellowships for foreign study have been awarded to men and women in Austria, Belgium,

Czechoslovakia, England, France, Netherlands, Hungary, Jugoslavia, and Poland.

"Until the autumn of 1922 it had not seemed necessary to grant fellowships to men for study in their own countries, but the plight of medical scientists in Germany and increased cost of research menaced the quality if not the very existence, of German medical science. A program of emergency relief was adopted by the trustees in December, 1922.

Tonic and Food Values in Citrus Fruits

The great achievement of the present day, says Dr. J. R. Harris in the *International Journal of Surgery* is the knowledge of how to attain health through the use of appropriate foods. When properly nourished, the body is less susceptible to infection and less prone to periodic breakdowns.

Dr. Harris especially recommends the citrus fruits as containing just the acids that are needed to stabilize the system and keep it properly regulated. The juices of oranges and grape fruit contains a generous amount of nutriment in the form of pre-digested fruit sugar. They also contain a quantity of absolutely pure, distilled water and they introduce into the blood various mineral salts which have a regulating influence.

Oranges are especially useful in making up deficiencies of the diet due to a preponderance of refined foods. A positive mineral as well as vitamin deficiency can well exist in the absence of natural foods. In colds, fruit juices perform the function of neutralizing the excess of acid in the system, and at the same time they afford a source of lime, which stimulates body secretions and activates the white corpuscles to perform their function.

Citrus are placed seventh in a list of all foods named in the order of their relative importance. They rank even higher as a source of vitamins. In the juice of grapefruit there are two parts of vitamin B and three of vitamin C, while in orange juice there are one part of vitamin A, two parts of vitamin B, and three parts of vitamin C. Orange juice is a valuable addition to the milk dietary of babies. The old adage that fruit is golden at breakfast, silver at noon, and leaden at night is dead. Citrus fruits can be profitably taken at any time, and they are always digestible.

THREE FIELDS

*where the physician finds
fresh yeast valuable*

FOR CONSTIPATION: It stimulates peristalsis and at the same time softens the fecal masses. The use of yeast in constipation is steadily increasing, with increased recognition of the deficiencies of concentrated, artificial modern diets.

IN FURUNCULOSIS: Careful tests have demonstrated that yeast produces a definite leucocytosis, roughly proportionate to the amount of yeast ingested. Skin troubles of this type generally respond readily to the administration of fresh yeast.

MALNUTRITION: Yeast is the richest known source of Vitamin B. While in no sense a complete substitute for fresh vegetables, it offers

a valuable dietary supplement in many cases of debility due to malnutrition.

Best results are obtained by eating one cake half an hour before a meal or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk, or fruit juices.

A new authoritative book: Written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry, and therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing The Fleischmann Company, Dept. Y-23, 701 Washington Street, New York, N. Y.

Sewage Disposal Problem of Chicago

(Continued from page 599)

sludge the so-called "septic tank" has been devised, in which an aerobic bacterial action takes place in the settled sludge, resulting in disintegration of the solids and their conversion into such gases as carbon dioxide, methane, nitrogen, and hydrogen, or into soluble substances which pass off with the liquid effluent. Experience indicates that the actual reduction in weight of solid matter in such tanks averages perhaps 30 per cent. The volume of sludge is often not over 20 or 25 per cent that which would be produced from the same quantity of sewage in a plain sedimentation tank. In some instances it has been practically free from odor, but this is not invariably the case. Violent ebullition caused by gas escaping from the sludge has an unfavorable effect in that it forces into renewed suspension quantities of the finely divided solids and allows them to escape with the effluent.

In the tank devised by Dr. Travis a separate sludge, or "liquefying" chamber is provided. Through the sedimentation chamber 87.5 per cent of the sewage is supposed to flow in five hours and 12.5 per cent over weirs through the narrow openings into the liquefying chamber where it remains for fifteen hours, the theory being that a seeding with fresh bacteria, of the liquid in the lower chamber, is necessary to the satisfactory operation of the tank. This separation of the sludge was a step in the right direction. The Imhoff tank was then developed, in which the passage of any sewage downward into the sludge chamber was obviated by the use of slots through which the sludge slipped from the settling compartment and which also was so devised as to prevent the escape of gases to the sewage above. For the escape of the gases generated, vents were provided. The period of detention in the Imhoff tank may be something less than four hours, and the removal accomplished somewhere between 45 and 65 per cent of the total suspended matter. From this type of tank the sludge is removed only at long intervals and generally in a condition so inoffensive that it will not be objectionable when spread upon sludge beds. In fact its character is particularly favorable to rapid drying since the entrained gases which buoy it up when it is first spread upon

the beds, admit of the free passage away of the moisture, and as the gases become liberated and the sludge settles it is left quite porous.

None of the tank treatments so far mentioned, however, provides for the removal of the colloidal matter, or finely divided suspended matter which is capable of being gathered together in clots, or "coagulated." An effort to accomplish this has been made by Mr. Collins, an English engineer, who, in collaboration with Dr. Travis, devised the tank known as the "colloider." In the center of this wooden slats are suspended for the purpose of attracting the non-depositable suspended solids. These sluff off the slats and sink to the bottom, with the result that a greater deposition of suspended matter is obtained than would have been produced in a plain sedimentation tank. The introduction of some chemical like alum or sulphate of iron and lime, into the sewage may also be used to produce artificial coagulation. Some substances which have been used for this purpose are inert and merely aid the colloidal matter to precipitate, while others enter into chemical reactions with the substances in the sewage, throwing out of solution the dissolved chemicals. The degree of clarification by such means depends largely upon the quantity of precipitant used. The amount of sludge produced by this method is large, often as much as 0.5 per cent of the sewage treated.

After the tank treatments, if it is necessary further to remove the fine suspended colloidal matters and to oxidize the organic matter, the effluent may pass to a contact bed. This is simply a concrete chamber filled with broken stone, coke, cinders, or other similar material. This "ballast" as it is sometimes called, serves to attract the colloidal matter very much as do the wooden slats in the "colloider" previously described, and in this gelatinous coating oxidizing bacteria find a favorable habitat. These convert the organic matter into more stable organic and mineral substances, and also the settling solids are strained and retained in the interstices of the filter. Gradually these voids fill up and clog and in some cases after a few years of service the contact material has had to be renewed.

After the bed has become matured, or in other words, when the gelatinous film has been built up by suc-

cessive applications, sewage is applied in sufficient quantities to completely fill the voids in the ballast, and yet slowly enough so that it will not break up and disturb the bacterial jelly. The standing-full period of the bed must not be too long since the supply of oxygen will soon become depleted and putrefaction set in. Experience has shown from one to two hours to be satisfactory. After the sewage has been drawn off by means of the underdrains, the standing-empty or rest period follows, when the bed regains its supply of oxygen and the organic matter left in the interstices of the bed becomes oxidized by the bacteria in the gelatinous film. As this is the period during which the most important biological action takes place it should be extended as long as is practicable.

The Trickling Filter

These beds are often operated in series or in alternation. The effluent from them, however, is not always sufficiently stable to admit of its discharge into some streams where the flow would not afford sufficient dilution, so the trickling filter has been contrived, for obtaining a still higher degree of oxidation. This filter may be constructed with a false floor consisting of grooved channels covered with slabs, to provide free spaces through which the water may drain away. Over the slabs is placed coarse stone of specified size, usually from 1 to 3 inches, and then on this a layer of broken stone, broken slag, cinders or other material, broken stone being most common in this country. The depth of the bed is usually 5 to 10 feet. Through such a bed the sewage is allowed to trickle continuously and as it is delivered by sprays or jets it is continually carrying into the interstices of the bed a fresh supply of oxygen, thus reducing the danger of putrefaction. The action within the bed is practically the same as that in the contact bed, except that the trickling filter is self-cleansing, the oxidized sewage passing down through the bed until it drops through the floor grating into the underdrains.

There is a seasonal variation in the efficiency of these beds which is very interesting. In summer oxidation is more active than during the winter, and with the first warm weather of spring there is usually a

To Relieve Weak Foot, Muscular and Ligamentous Strain

The symptoms of these conditions are tired, aching feet, tender heels, cramped toes, rheumatic-like pains in the legs and bodily fatigue. For such cases Dr. Scholl's Foot-Eazer should be prescribed. It is light in weight, self-adjusting, comfortable to wear and gives just the right pressure at the right spot. By removing the unnatural strain, which is always present in cases of weak foot and incipient flat-foot, Dr. Scholl's Foot-Eazer gives immediate and lasting relief.

Dr. Scholl's Foot-Eazer is only one of

Dr. Scholl's ***Corrective Foot Appliances***

Leading shoe dealers and surgical instrument houses in all parts of the world, through special training are prepared to follow accurately physicians' instructions. There is a Dr. Scholl's Corrective Foot Appliance for each specific foot condition, adjustable to meet the individual requirement of each particular case. Dr. Scholl's Appliances are worn in the regular size shoe—no special shoe—no plaster casts required; for heavy persons, for growing children, and those constantly on their feet.

Manufacturing Laboratories, BLOOMFIELD, N. J.

ganic matter which it contains. The filter should be dosed at such a rate as to insure covering the entire area to a depth as nearly uniform as practicable. As 27,000 gallons applied to one acre, if all held upon the surface, would correspond to a depth of only about one inch it is the practice in some places to dose the beds but once in two or three days, and apply a heavier dose.

Distribution over sand filters is effected either by troughs with hinged wickets, running lengthwise or radially across the beds, or by outlets set at the corners of the beds or at points along the sides of the beds. In many instances the construction of sand filters is impracticable because of the prohibitive cost resulting from the necessity for importing sand, the small volume of sewage which can be treated on a given area, or the high labor cost involved in the removal of the surface mat.

Activated Sludge Process

But the newest method of sewage treatment is that known as the activated sludge process. For quite a number of years a most elaborate series of tests and investigations have been carried on with it at Milwaukee.

Figure 3 gives a general idea of the drainage system of this city—the three streams discharging into the lake at about the center of the picture, in a general way paralleled by a system of intercepting sewers. Prior to the building of these collecting sewers the sewage was discharged into the rivers and some of it directly into the lake. From September 16, 1874, until September 25, 1895, the city took its water supply from a point indicated on the map as the intake of this period. Later the source of supply was extended to another intake nearly three miles from the harbor entrance, or the mouth of the rivers; and more recently still it has been extended to a distance of some four miles. Yet analyses have indicated that the sewage does reach even to this most remote intake.

For that reason and to clean up the rivers the city of Milwaukee undertook the investigation above referred to and is now proceeding to build a municipal plant on a small plat of land known locally as Jones Island, where it will treat the sewage by the activated sludge process.

I have spoken of the removal of the colloidal matter in the sewage, by the use of colloids or by the addition of chemicals. The principle of the activated sludge treatment is similar, except that instead of adding chemi-

cals to produce coagulation sludge which has been "activated" is introduced for this purpose. This sludge is produced in so-called "aëration tanks," with porous bottoms, such as filteros plates, through which the air is forced upward in such quantity as not only to sustain aërobic bacterial activity but also to produce constant agitation of the sewage in the tanks," with porous bottoms, such as clots of the fine suspended matter and colloidal substances in the sewage, results, and this sponge-like clot sweeping through the liquid exerts a straining action upon the colloidal substances. The bacteria, also, contained in the clot feed upon the finely divided matter entrained by it, thus relieving it of its burden and restoring its power of absorption. Were it not for the continual agitation of the liquid in the aëration tank these clots would settle to the bottom, form sludge and clog the air distributing system, but the mixed liquor flows from this tank to a sedimentation tank where such settlement is allowed to take place and from which the accumulated sludge (containing the clots with their active bacteria) is withdrawn and a portion of it returned, by means of pumps, to the incoming sewage before it enters the aëration tanks. The proportion of sludge thus returned is generally about 20 per cent of the volume of the sewage.

In the initial treatment before such sludge has been accumulated, it may require a number of days to secure the requisite quantity and character of sludge for the treatment of the raw sewage, but after the process has once become established and the sewage has been treated with some of the sludge from the preceding treatment, it goes on in a very short period of time—roughly six hours.

At Milwaukee the sewage enters the sedimentation tank at opposite sides, the effluent flowing away over the tops of suitable troughs and out into the lake. The sludge is drawn off from the center through a conical hopper and pipe, a portion being returned to the incoming sewage at a point near the outlet from the screen chamber, and another portion to the sludge recovery process.

If this process be carried sufficiently far the sewage may be converted into a relatively pure water; not a water that is suitable directly for drinking, but one which will not putrefy and from which a very large proportion—perhaps upwards of 95 per cent of the bacteria may have been removed.

Profit in Fertilizer

An interesting feature of this process is that the sludge obtained contains a relatively large proportion of nitrogenous matter, or plant food. There is, therefore, the possibility of utilizing this waste product, and this is the only process which gives promise today of affording a profitable commercial fertilizer. I do not mean to infer from this that enough can be recovered from the fertilizer to pay for the entire process, but it is possible that enough can be obtained to pay for dewatering, drying and disposing of the sludge, which is a very distinct advance over most of the other processes now available.

While the amount of sludge produced by any process will vary materially with local conditions and with the amount of solid matter removed from the sewage, it is recognized that the activated sludge process under all conditions will produce a very much greater volume of sludge than any other process. For the disposal of the major portion of this sludge (or such as is not returned for treating the incoming sewage) there are various methods. At Houston, Tex., sludge lagooning has been successfully utilized.

A Partial Solution

Dewatering has also been tried, and extensive experiments have been carried on in this connection, at Milwaukee. Various types of apparatus have been used—the plate press, the squeeze press, the centrifuge and the vacuum filter. The first of these is formed by a number of cells each made by two adjoining cast iron concave plates brought closely together, to prevent the sludge from squirting out between them, and with their faces covered with cloth. The sludge is pumped in at one end, passes through a central channel, and into the several cells. After pressure has been exerted and the sludge is relatively free from water, the plates are drawn back, one at a time, and the cake which lies between the cloths is dropped out. With the sludge in its most favorable condition for pressing, a cake about one inch thick may be obtained in something like two hours. Sometimes, on the other hand, it takes from four to five hours for the cake to form and then it may be so wet that it can be removed from the cloth only with difficulty and leaves it soiled and smeared. This slimy quality of the sludge has in some instances been counteracted by the addition of acid before pressing.

The squeeze press is quite different

Do you ever question your sterilizing methods?

Every treatment or examination room needs a sterilizer that will prevent chance of infection from unsterile articles. If you did all your work at the Hospital you would never think twice about this danger.

Now you can have that same surety with the use of Castle sterilizers. They are safe because they are made right in every particular—and have been for thirty years. They are a credit to any operator.

"Every patient looks for a sterilizer"

CASTLE

Complete line of Physicians', Dental, Hospital and Bacteriological Sterilizers

WILMOT CASTLE COMPANY, 1153 University Ave., Rochester, N. Y.

No. 1416

This new unit has a 10" instrument sterilizer, 3-gal. water sterilizer, a table top and cabinet. Neither sterilizer can boil dry. Single action lift for cover and instrument-tray. Three way faucet allows sterilization of water in the gauge glass. Even if you have a sterilizer send for catalogue "H"

in principle, consisting of a number of bags, open at the bottom and held by supports at the top. Between each pair of bags a corrugated drainage rack is suspended. Before filling, the bottoms of the bags are forced together to prevent the escape of the liquid sludge, and then the sludge is fed slowly in through small flexible tubes. When the bags are full the inflow is shut off and pressure applied to all the bags by means of end platens, the squeezed-out water escaping through the vertical corrugations in the drainage racks. This method may be carried on with sludge in a less favorable condition for pressing than where the plate press is to be used, but it takes longer, seldom being accomplished in less than four hours.

In one form of centrifuge the sludge flows into a revolving drum open at the top. The cake is formed directly upon the side of the drum which upon completion of the formation of the cake can be mechanically raised and the cake then thrown out of the drum by centrifugal action. The water in turn is thrown upward and escapes over the top of the drum.

In the case of the vacuum filter, which is the machine finally adopted at Milwaukee, the sludge after treatment with acid and heating flows into a box within which revolves a canvas duck-covered drum, so arranged that the portion below the surface of the sludge is under a vacuum. As the water is drawn through the duck into the drum the solids accumulate upon its surface, and as the drum revolves the section upon which the cake has been formed rises above the surface of the sewage and enters into a zone of reduced vacuum by means of which the moisture in the film of cake is somewhat reduced. From this zone of partial vacuum the drum section bearing the cake then enters a zone of steam or air pressure, the pressure being applied to the inside of the drum. This loosens the cake which then passes beneath a knife-edge by which it is scraped from the drum.

Plants Made Attractive

There have been a great many objections to sewage treatment plants. The public does not take kindly to having them located near the cities, and individuals dislike to have them located near their property. In some cases they have proved sources of objectionable odor, and in the case of trickling filters the very large numbers of little moth flies which make their home there, are most annoying in the immediate vicinity of the filter.

But, after all, it is probable that the most serious objection to the sewage treatment plant of today is a sentimental one. If there were absolutely no odor, if there were no flies or anything else which might even suggest objectionable conditions, there would still be a sentimental objection to having a plant for the treatment of the municipal wastes, located near one's property. And so it is important that engineers should take this into consideration and make the plants as attractive as possible. Ordinarily, this does not involve a serious expenditure, and it is well worth the cost.

A Partial Solution

The problems presented to the board of engineers who were asked to advise the Sanitary District with reference to the treatment of the sewage of the North Side of the Sanitary District involved a number of questions, such as the degree of purification which would be required, the location of the plant, and the type of plant which the District should procure. The sewage from this District will be collected at a point along the North Side Channel, by means of sewers which are very deep and very large. To carry the sewage a great distance involved heavy expense, so it was considered advisable to treat the sewage in that general locality, which approximately is west of the city of Evanston.

Various processes were considered and some were eliminated with very little study, because they were entirely impracticable for the local conditions; sand filters, for example, which would have involved an enormous area and an expense entirely prohibitive; and, for the same reason, contact beds.

There were, however, two processes to which serious consideration was given. One comprised Imhoff tanks for removing the coarse materials, with subsequent treatment on trickling filters, for oxidizing the remainder of the organic matter. The other was the activated sludge process.

In view of the proximity of the sewage treatment site to the city of Evanston, and of the certainty that the District in that vicinity will increase greatly in population in the future, together with the importance of providing a comparatively pure effluent to be discharged into the North Branch, the Commission decided in favor of the activated sludge process. This can produce a treated sewage which will be practically clear, free from color, free from odor, and will not cause objectionable conditions in

the channels through which it passes to the Illinois and the Mississippi rivers.

This is an expensive project, involving some thirteen million dollars and, while complete in itself, does depend in a measure upon future development.

In regard to the disposal of the sludge the Commission advised that it be carried a relatively long distance through a force main and disposed of for the time being by lagooning at the westerly portion of the District near the main channel, with the thought that ultimate development of the process of dewatering and drying the sludge might make it practical to replace this measure by a sludge recovery process at some future date. The Commission had no fear, however, that the method which it recommended for immediate use would not prove entirely satisfactory, although some better method may develop later.

An Unpopular Subject

In the matter of sewage treatment there are several difficulties. It is an unpopular subject. No municipality desires to spend money for the benefit of its neighbors, and this is, almost without exception, the case in matters of sewage treatment. Yet this subject must be considered from the broad point of view—that the cities and municipalities are merely arms of the state. The state is the entity which has to do with this problem, and the municipality is simply carrying out the directions which are provided by the state. While the treatment of sewage and the disposal of other wastes is unpopular, much can be done by the engineer to improve the status of these problems. The best of design and the best of operation are necessary to the success of these undertakings. The engineer who acquaints himself with the problems, though he be not directly connected with them in his daily work, can exercise his influence toward assisting in securing conditions which will permit of the best of design, the best of construction, and the best of operation, of which probably the latter is the most important.

A statement which has just been issued by Frank T. Hines, director of the Veterans' Bureau, gives out the figures that approximately twenty thousand more disabled veterans will have been rehabilitated by January 1, 1924. About eighty thousand men are now undergoing training.

Avoid Breakage at the Knot

by Using *Armour's* Non-Boilable Surgical Catgut Ligatures

They possess every quality the surgeon looks for, tensile strength, pliability, smoothness, absolute sterility. They are made from lambs' gut selected for surgical purposes.

WHEN Pasteur made his great discovery which brought about the Pasteurizing of milk, it was a tremendous scientific step toward greater purity. When Heath made his remarkable discovery of Heathizing Ice-Cream, food scientists acclaimed it as an equally momentous achievement.

HEATHIZATION is the newly discovered method of making ice-cream in an atmosphere of purity and cleanliness. In making Heathized ice-cream, the ordinary air is driven out of the freezers and replaced with a clean, pure and sterile atmosphere. The result is a more delicious tasting and better flavored ice-cream. The texture of the ice-cream made this way is richer, more creamy, more appetizing.

UT, above all, Heathization is a sanitary precaution. It protects the purity of ice-cream. There is a manufacturer of Heathized Ice-Cream in your city, so look for this "Sign of Purity" when buying ice-cream. If your dealer hasn't it, ask him to get it for you, or write us for further information.

Protection Against Dust and Fumes

(Continued from page 601)

Brass founder's ague is a well-known example of the poisonous effects of metallic (zinc) fumes. It is an acute ague-like attack, coming on usually after exposure to the fumes of molten brass but frequently not until after the man has left the shop and gone into cold air. He suffers from a severe chill, weakness, nausea and then fever, sweating and prostration but generally he is able to return to work the next day and hardly ever considers the attack serious enough to send for medical assistance.

Carbon monoxid, which is found in coal gas, in illuminating gas, and is produced in many industrial processes, is a common cause of both acute and chronic poisoning. The acute form is becoming more frequent and often occurs where gasoline motors are allowed to run in a closed space. The inhalation of carbon monoxid gas causes headache and a sense of loss of power in the lower extremities. There are also dizziness, throbbing of the temples, buzzing in the ears, a sense of weakness, and, in severe cases, loss of consciousness and death.

Benzol poisoning is another industrial health hazard that has become common in recent years. It enters the body as a vapor, irritates the respiratory tract and produces acute and chronic poisoning. In acute poisoning the symptoms are coughing, vertigo, ringing in the ears, vomiting, perspiration, itching, irregular pulse, etc.; in severe cases convulsions, coma and death; in the chronic form hemorrhages in the skin, destruction of the blood cells as well as changes in certain internal organs and in severe cases death.

The foregoing are cited simply as examples of the effects of varying types of fumes upon the body. The list could be lengthened indefinitely.

The methods of protection against the harmful effects of dust and fumes is a matter of great importance. Briefly, we may consider them under two headings: General measures and specific measures.

Means of Protection

As general measures for protection against dust and fumes we have:

(1) *Industrial Law.*—The foundation of industrial hygiene and sanitation rests on industrial law. The history of the control of industrial hazards is the history of the enactment of industrial laws. Industrial laws

must be scientifically sound. Fundamentally, the law is for the protection of the worker but on the other hand, in forming such a law the effect on industry and the cost of production must be considered. The elimination of all dustiness in the work processes where there is a dust hazard may be desirable but there is no scientific reason for such a requirement if the dust itself is not a specific poison.

It should be borne in mind that the enforcement of laws regarding industrial hygiene is largely a matter of police, power of the State and is not a function of the federal government. The function of the federal government in this matter is to make studies and researches and from these the several states may form the proper laws and regulations for the safeguarding of the health of those engaged in industry.

(2) *Law Enforcement.*—Industrial laws are valueless unless enforced. The method of law enforcement in industry is usually through factory inspection and the actual checking up of the efficiency of the protective devices. Competent factory inspection insures the control of industrial hazards and the maintenance of acceptable sanitary conditions.

(3) *Education.*—The worker needs to realize the danger of certain health hazards as well as the employer. Protective measures may be required by law and provided by the employer but if the worker does not understand the necessity for their use much of their protective value is lost. Wholesome, common sense education is the means by which the need for intelligent use of protective measures is impressed upon the workers.

(4) *Scientific Study of Industrial Hazards.*—The correct basis of industrial law rests on comprehensive scientific understanding of the hazards that are to be controlled. The proper control and prevention of the health hazards of industry and their effect upon the health and physical condition of the worker can be obtained only through careful and thorough scientific investigations. The maintenance of adequate industrial sickness records by employers in order to determine the cause of sickness among workers and to measure the efficiency of measures used to reduce health hazards is an important part of the study of industrial hazards.

Specific measures for the control of

"400"

For Schools

The Chocolated Dairy Drink

"400" is a chocolated dairy drink, blended fresh daily by local dairymen.

The syrup, the flavor, the formula and process were evolved by Walter K. Jahn, in consultation with numerous health authorities.

It was originally made for schools, to correct and prevent malnutrition. To induce children to drink more dairy products than most of them will drink in plain milk.

The drink proved enormously popular. Millions of bottles are now sold at soft drink counters, and delivered to homes with the milk.

Wherever well known, "400" has become the favorite drink with children.

"400" is a fifty-fifty blend of fresh whole milk and fresh skimmed milk, plus 10% of Walter Jahn's chocolated syrup.

The butter fat content is 2 per cent.

It is blended by the viscolizing process, under enormous pressure, to break up the globules of fat.

The flavor is unique and enticing.

The product is pasteurized, then put up in milk-type bottles branded "400" on the bottle and the cap.

The cap permits drinking through a straw without removal of the cap.

The 7-ounce bottles usually retail at 5 cents. There are also pints and quarts.

Health authorities are requested to investigate this product, as many have already done.

Local dairymen in most sections now blend and deliver it daily. We will arrange for supplies to any community which wants it.

Wide experience proves that this drink, vastly increases the consumption of dairy products, and that it also leads to great increase in the consumption of plain milk.

Write us for details.

Promote Health Through Entertainment and Instruction

Almost everyone engaged in promoting health—whether of individuals or the public—can use the moving picture as a means of entertainment or instruction.

Many hospitals, sanitariums, public health officers, etc., are applying this powerful agent with marked success. They are entertaining convalescents, instructing mothers in the care of babies, rebuilding wounded soldiers, promoting "swat-the-fly" campaigns, and a dozen other things that might be enumerated.

A great deal of film adaptable to such work is now available. And with a projector like the Acme, guaranteeing pictures equal to theatrical standards, and at the same time easily portable, you can get the maximum use out of a film. The Acme exclusive gold glass shutter is another big advantage since it enables you to stop anywhere on a film and show a still picture with no danger whatever.

Have you made a careful study of the value of moving pictures for your own work? Let us talk it over with you. Our long experience with the uses others have made of films enables us to answer many questions that are doubtless in your mind. Use the coupon for your own convenience.

THE WESTERN COMPANY - Chicago, New York

dust and fume hazards are: (1) General or special ventilation systems which include general ventilation and the collection of dust at the source by means of ducts and exhaust systems. (2) The use of respirators, masks or hoods. (3) Development of manufacturing processes that will largely eliminate the production of dust and fumes. (4) Periodic physical examination of workers.

Mention can be made here of only the last item, periodic physical examination of workers. Such physical examination of workers exposed to health hazards should be made at regular intervals in order to determine any early symptoms of the effects of the dangerous processes or hazards to which the worker is exposed. This matter of making at regular intervals physical examinations, although one of the most important matters in the prevention of health hazards, is perhaps the most difficult to accomplish. Workers in the beginning invariably regard it with suspicion and it is only after long and careful effort that workers are convinced that such examinations are for their own good and are not intended to be used as a means to discriminate against them or to discharge them. After a company has shown that the periodic physical examination given the worker in hazardous processes is intended for the benefit of the worker, experience has shown that the workers become enthusiastic supporters of the plan.

The elimination of health hazards due to dust and fumes from all industrial processes is perhaps impossible but the foregoing suggestions may contain some ideas which it is hoped may prove helpful.

Physical Education Activities of Newark Y. M. C. A.

Twenty-five hundred members of the Newark Young Men's Christian Association regularly use the privileges of the physical department, gymnasium, natatorium, boxing classes, and massage department.

A score of organized groups such as industrial teams, boys' clubs, boy scouts, Sunday school and church teams, Sunday men's organizations and public school teams often use the Y. M. C. A. physical privileges without any expense to them.

In handling this large number of activities within its building, the Newark association has on its physical department staff a director of physical education, three part time gymnasium instructors, two volunteer leader-directors, and one director of

massage with two part time assistants.

From seven to eight hundred members daily use the various physical features—gymnasium, classes, basket ball, track, gymnastics, wrestling, handball and swimming teams.

An interesting part of the association program has been the development of a volunteer leaders' corps. The members of these groups are nearly all qualified to direct large or small classes of men or boys in a complete "gym" class program. There are about forty of these members and they wear a distinctive uniform while leading squads or classes in the department. For the past six or eight years five of these leaders have gone into active work as physical directors, some in public school departments and others in association work.

Corrective gymnastics, Swedish massage, electric baths, aquatic instructions, life saving classes and sex instructions are provided many of those members who desire those special features.

Outside of the association, the physical directors have received generous welcome in industrial plants, insurance, offices, churches, Sunday schools, community centers and elsewhere where they have been instrumental in promoting many programs of noon-hour recreation, social and athletic activities and a comprehensive recreational program.

Wherever physical activities are presented in and around Newark, the Association Physical Department seeks to and does have some part in the conduct of such activities because its committee believes that the Y. M. C. A. must serve everybody, everywhere and at all times to justify the support tendered it by its many friends.

Last year more than one hundred and fifty thousand men and boys in Newark were in some way included in the association physical program, according to information received from Mr. Frederick W. Ball, chairman of the Physical Education Department.

The second report of the Association for the Prevention and Relief of Heart Disease is an account of considerable achievement. Particular interest centers in the establishment of forty-three out-patient classes devoted to the diagnosis and treatment of heart diseases, the opening of convalescent homes to the heart cripple, the work in the public schools, and work connected with suitable industrial placement for those with damaged hearts.

Outbreak of Food Poisoning

An outbreak of food poisoning among Yale University students is reported by Winslow, Hiscock, Rogers and Robinson (*Am. J. Hyg.*, May, 1923, 3, p. 238). The outbreak totaling fifty-one cases was due to *Bact. paratyphosum B* in an egg salad. The lettuce in the salad was apparently not responsible and, though the causative organism could not be detected in the feces or urine of the cook preparing the dish, there were reasons for suspecting that he was at the time a temporary carrier. The disease affected five-sixths of those who ate the dish and "caused an acute gastrointestinal upset, coming on from twelve to thirty-six hours after ingestion, and lasting from three to six days, with headache, abdominal pain, fever and usually diarrhea."

Persistent Diphtheria Carriers

Sumner believes that the use of antitoxin prophylaxis in diphtheria is a "two-edged sword," producing many healthy carriers—those who have never had any symptom of the disease but persistently harbor organisms.

These conclusions were derived from the study of an epidemic among two hundred school boys, in Simla, India. After the epidemic was under control and an interval of two months had elapsed, several sporadic cases led to the examination of 80 of the students who had never had the disease following prophylactic doses of antitoxin. Fifty per cent of these were found to be carriers. (*Brit. M. J.*, May 12, 1923, 3254, p. 808.)

Indices of Nutrition

An interesting study of indices of nutrition has been made by Clark, Sydenstricker, and Collins (*Pub. Health Rep. June 8, 1923*, 38, 23, p. 1239). From a large number of children were selected 506 of native parentage and native grandparents; with no physical defects; and with good or excellent nutrition as judged from clinical evidence. Three standards of weight were then applied to these children who were, as far as a careful physical examination revealed, in good health. According to the Wood standard (height-weight-age tables) 20 per cent were more than 10 per cent underweight; according to Dryer's standard (stem length and chest circumference tables) 13 per cent were more than 10 per cent underweight; and according to Pirquet's "pelidisi" method, 17 per cent were

shown to have a pelidisi of 94 or less.

Many individuals classed as underweight by one standard were classed as normal or, in a few cases, overweight, by one or both of the other standards. "Out of 506 children, 210 were classed as underweight by one or more of the three standards used; of these 210 cases, all three standards agreed on 15 cases as being underweight."

It should be remembered that all these children were selected as the best specimens of health that could be found among school children and that in spite of this fact one-fifth of them were underweight according to the standard most frequently used in schools.

Scarlet Fever in Juvenile Home

Griswold reports (*Am. J. Pub. Health, June, 1923*, xiii, 6, p. 465) on an epidemic of scarlet fever that occurred in a state juvenile home. The outbreak began in a rather unusual manner. One of the matrons belonging to "a peculiar religion sect that denies the existence of disease" advised a sick child not to report to the physician who makes daily calls at the institution. Shortly after the rash appeared the child was secreted in the matron's room "so that the other children wouldn't get the false idea that she was sick."

As soon as the rash disappeared this girl was allowed to mingle with the other inmates and 33 cases developed. Only one of these can be suspected of being caused by an indirect contact or by contact with an inanimate object.

Appalling Death Rate in India

A London Correspondent (*J. A. M. A.*, May 5, 1923, 80, 18, p. 1324) writes that during the decade 1910-1920, of the population in India subject to registration, amounting to 228,500,000, "3,500,000 perished from plague, nearly four million from cholera and nearly one million from smallpox—a yearly average of 800,000 deaths from preventable disease. In addition one million have died annually from malaria, which also is preventable. The general death rate excluding the exceptional year of influenza prevalence, when the ghastly rate of 62.46 per thousand was recorded, in four years of the decade amounted to 30 per thousand, or within a fraction of that figure; in four years this was considerable exceeded; the lowest rate, attained in but one year, was 28.72.

Public Health Developments in Siam*

*A Country Where Causation and Cure of Disease Are Still Greatly
Confused by Belief in Malevolent Influences Rather
Than Sanitary Factors*

BY M. E. BARNES, M.D., THE INTERNATIONAL HEALTH BOARD, SIAM.

LYING as it does outside of what have hitherto been the usual lines of travel, little is generally known of the kingdom of Siam. The history of its peoples has never been extensively studied, but we know that the Thai race in ancient times lived in the western part of China where even today, in the Yunnan Province, large numbers of this race still remain. Chinese records indicate that at a period approximating the time when Abraham set out from Ur of the Chaldees, there was a large emigration of Thai peoples from their ancestral home owing to the pressure of invading Mongols. During the succeeding centuries these peoples gradually moved southward into Camodia and later into what is now called Siam, where they carried the language and customs of their original civilization. They adapted themselves to the peculiar conditions of life in their new home and became, and still re-

main, almost exclusively an agricultural people.

Their agricultural life has been devoted almost entirely to the cultivation of rice. This has been due, among other causes, to three important factors: the physical features

made the people the chattels of the "Chaos," who were absolute rulers in their realms. Under this system individual accumulation of wealth was not altogether to the personal advantage of the individual. The great majority of the people were content

to raise only sufficient food for themselves and their families. He that gathered much had little over (for it was ever subject to the whims of the ruling Chao); he that gathered little had no lack (for as a general rule food has ever been plentiful and easily obtained in this country). The incentive necessary to lead men to work out new methods of agriculture was not provided under this system. Fortunately, the people throughout the entire country have in recent years been freed entirely from this

Filter plant at Bangkok Water Works.

of the land, which make rice-growing the easiest form of agriculture; the sparsity of the population, which has always enabled the people to escape the stern struggle for existence obtaining in China and India; and the traditional form of government, which

repressive form of government, and under the stimulus of more favorable conditions, a new spirit is rapidly developing which is destined to affect the whole nation.

These things are mentioned here because of the light they throw upon

*The observations upon which this paper is based were made with the support and under the auspices of the International Health Board of the Rockefeller Foundation.

ferent as to what may be beneath their houses. The simplicity of their habits of life constitute a further problem. Whole communities dwell in boats on the rivers, and the remainder of the population contributes to the pollution of every stream. Yet many of Siam's millions are at present dependent for their drinking water upon these same streams which they pollute. If people insist upon dwelling in what are for many months of the year veritable swamps, it is not a simple matter to recommend practicable sanitary provisions by which health conditions may be improved.

The greater part of the village population lives in bamboo houses which are durable, comfortable, and economical. It is difficult, however, to protect these houses against rats, and no practicable method within the financial reach of the owners has yet been evolved to prevent the ingress of flies and mosquitoes.

In spite of the fact that from their earliest history the Thai people have never known any form of government other than an absolutism, they are remarkably jealous of their individual rights. It is futile to attempt to coerce them. They are open to reason, however, and when they have been thoroughly convinced that measures are desirable, it is not difficult to persuade them to adopt reforms, provided these are presented to them in the proper manner. It requires the activity of the local government officials exerted in a paternal rather than an authoritative, spirit to initiate the reforms; but these officials have plenty to do along other lines and do not always give the emphasis to health matters that is needed. Progress is thus necessarily slow.

Although undoubtedly there is in the country a public opinion that on certain subjects is quite definite, there is very little opportunity for the expression of this opinion. Consequently, it is not as yet a factor in the support of health work. The education of a definite public conscience relative to health

matters is one of the fundamental tasks that lie before the health authorities of the country.

The paucity of properly trained health officers is a serious handicap.

New sanitary latrine as installed in villages.

Opportunities in other lines have been so much greater than in public health work that the number of men entering this field has been small. Health work has therefore been developed under a heavy handicap. As one administrator remarked recently, "We have men occupying positions which call for far greater ability than these men possess, but what can we do? It is like putting in a five horsepower engine where a fifty horsepower engine is needed. The little engine does the best it can, but it can only be expected to do work up to its limit. With the reorganization of the medical school now possible through the help of the Rockefeller Founda-

people. This has led to a great influx of other races who find excellent opportunity for gain in the country. The Chinese far outnumber all other foreign peoples in Siam, and each incoming ship from China brings a load of immigrants. Most of these settle in the vicinity of Bangkok where they establish living conditions similar to those prevailing in their homeland. The better class of these industrious people have built up excellent commercial ventures, and practically control the exportation of rice. The lower classes transform the unoccupied plots of ground into vegetable gardens (fertilized with offal), piggeries, duck farms, and similar remunerative nuisances, to the disgust of those compelled to be their neighbors, and to the despair of the health authorities, who at present are powerless to abate the nuisances.

Development of Health Work

Keeping in mind the conditions mentioned above, the specific advances in health work are much to the credit of the country, even though the health officers who are building it up are impatient over the enormous amount that remains to be done. Health work may be said to have only begun, but it has made a good start.

During the past year, an amalgamation of ministries took place resulting in the establishment of a really national department of public health, which, albeit imperfectly, reaches the greater part of Siam. A scheme of reorganization that is now being effected fundamentally changes the emphasis from curative medicine to preventive medicine. The scheme provides for the carrying out of such health activities as are national in their scope and such as the department is at present in a position to carry on under the following five sub-departments:

(1) Central administration. Under this head is included Government Medical Depot and the administrative control of importation and distribution of all habit-forming drugs—(Continued on Page 737)

tion, we hope to have an increased number of capable men."

The heaviest immigration is from China. The Thai people are an agricultural rather than a commercial

The United States Government and the Disabled

Nineteen Class "A" Dispensaries Exist Along With Seventeen Dispensaries of the Class "B" Type. The New York Clinic Described Is a Model for All the Others

By W. F. LENT, DISTRICT MANAGER, DISTRICT NO. 2, U. S. VETERANS' BUREAU, NEW YORK CITY.

AFTER the ecstasy of the armistice had subsided and our soldiers, sailors and marines were gradually being discharged from the service, the realization dawned on our government that there were new responsibilities that it would have to meet. Millions of ex-service men were preparing for their reabsorption into civilian life and thousands of them were disabled in some form that would prevent re-employment. It was up to our country to see that these men were aided in their re-entry into the industrial, commercial, and professional worlds and to see that those disabled were cured, where humanly possible. It was the latter phase of this problem that impressed the country at large. It was a problem that remained as such for three years after the armistice. The United States Public Health Service and the contract hospitals were doing the best that they were able, but having no dispensaries for the treatment of ambulatory cases was a big handicap. It was recognized that the establishment of clinics and additional hospitals would eventually be an absolute necessity so that, with the passing of the Sweet Amendment to the War Risk Insurance Act, on August 9, 1921, calling for union of the Federal Board of Vocational Training, the War Risk Insurance Bureau, and Veterans' Relief functions of the United States Public Health Service into one body, to be known as the United States Veterans Bureau, it was decided to prepare immediately for establishment of these clinics. The Sweet Amendment, among other duties, charged the new Bureau with the responsibility of pro-

viding proper medical care and treatment, as well as compensation and vocational training, for all men or women disabled in service since April 7, 1917.

Then began the long and arduous preparations for the founding of these clinics. The great medical leaders of

aries of three different classes, the class of each depending upon the population of the center to be served. It was determined, after a survey, that there would be nineteen Class "A" dispensaries, all with the most complete equipment for every type of disease known to science, and manned

by the highest type personnel, so that all ambulatory cases would be accorded thorough and proper treatment. These Class "A" dispensaries exist in each of the fourteen districts in addition to five more in Pittsburgh, Baltimore, Kansas City, Detroit, and Los Angeles, large cities that are not the sites of District Offices. There were to be erected seventeen dispensaries of the Class "B" type (with not quite so extensive or complete an equipment as in the "A" class) in Providence, Newark, Buffalo, Rochester, Indianapolis, Louisville, Cleveland, Columbus, Milwaukee, Omaha, Salt Lake City, Portland, Spokane, Oklahoma City, and Houston. Approximately 104 dispensaries, corresponding to a standard Class "C" clinic, were also to be installed.

This plan was finally passed on and adopted in January, 1921, and the work of installing the clinics begun. Included among

the nineteen of the "A" type was that one to be developed in the district office of New York City. It was decided to equip this particular clinic with the highest human and scientific agencies that could be found and to establish it as a model for all other Class "A" Veterans Bureau dispensaries. A site for the clinic was selected on the eighth floor of the Grand Central Palace building, the highest type of personnel engaged and plac-

Mold room in orthopedic section, showing Veterans' Bureau trainee making mold of patient's deformity.

the country were called into consultation to outline a program that would be suitable as a basis for such service in each of the districts of the Bureau. There were fourteen of these districts situated in the largest cities of the country, each one having jurisdiction over a large territory, through which were scattered sub-district offices. It was the plan of the promulgators of the clinic program to create approximately two hundred dispens-

ing of the most modern scientific apparatus begun. Its installation proved to be most laborious as much had to be done at night due to temporarily insufficient elevator service in the building. There were times when the most delicate of apparatus had to lie in the street for twenty-four hours at a time. Partitions had to be razed, others erected to fit the scientific floor plans devised, in order that space, light, and air might be utilized to the fullest.

Finally, however, in September, 1922, after months of intensive effort, clinics (Medical, Eye, Ear, Nose, and Throat, Orthopedic, Physio-therapy, x-ray, Dental, Tuberculosis, Psycho-Neurosis, Surgical, and Laboratory, etc. in all) were declared ready for operation. There were appointed thirty-one general examiners, dentists, nurses, physiotherapy aides, laboratory workers and a clerical force making a total clinical personnel of one hundred individuals, with a salary list of \$150,910 annually. To ensure the most expert care of our invalid veterans a staff of medical and surgical specialists was organized to consult with the clinic physicians, and these specialists include some of the leading members of the metropolitan medical profession.

The dispensary of the United States Veterans' Bureau at New York City is, therefore, one of the most advanced and complete in the world, with many features wholly new in treatment, and the story of its development and installation is a record of devoted, but unsung effort on the part of men who worked tirelessly, day and night, in order that it should become the great human salvage plant that it now is.

Conspicuous in this dispensary is its "physio-therapy" unit that embraces all the newer approved physical means for bettering those injured or ill. Everyone who visited our war hospitals must recall the good results following extensive resort there to

these advanced aids in treatment, and the civilian public as well as ex-service men now are befitting from their general introduction. Let us visit the Hydrotherapy rooms of the

ty of low and high tension electrical currents are used to stimulate and regenerate muscles and nerves, is another recently broadened out development of present day physiotherapy.

Here, through carefully induced, delicate contractions, these new currents increase the tone of enfeebled muscles and very gradually overcome the atrophy that arises from longtime enforced disease of injured limbs.

The largest portion of this interesting physiotherapy clinic is found in its "general treatment" hall, where applications are made for a wide range of affections bone and joint disabilities so numerous in our battle-injured, bronchial diseases, pleurisy and other chest maladies, nasal disorders, diges-

tive ills, and ailments involving almost every part of the human body. In this section, for example, there is the diathermy treatment with high frequency currents that cause through-and-through heat penetration found so useful in a great variety of medical and surgical conditions; in regeneration of bone defects after accident or operation. This treatment is furthermore utilized here to eliminate waste products of the body to build up strength after debilitating sickness, or injury and, not of least importance, to stabilize blood pressure. Other features of the room's equipment are the deep therapy lamps that do away with heat rays but allow the light rays to penetrate, being of great aid in neuritis, sciatica, and kindred painful affections.

Another section of the physiotherapy unit is the Ultraviolet Ray Room where air and water cooled ultraviolet ray lamps are applied to kill bacteria in local infections, for skin lesions, and to create a general upbuilding and tonic effect in debilitated states of the human body. The

ultraviolet ray lamp is a delicate instrument, so that all treatments given by it are accurately gauged as to time of application and distance from the body—(Continued on Page 739)

liminary warming up of wasted parts of the body so that subsequent electrical or other applications may be fully effective.

The galvanic rooms, where a varie-

The Training of Health Workers

The Contribution of the New York State Department of Health in the Training of Local Health Officers, Public Health Nurses, and Other Administrators of State Health Service

BY CHARLES C. DURYEE, SANITARY SUPERVISOR, NEW YORK STATE DEPARTMENT OF HEALTH; DIRECTOR, POST-GRADUATE COURSES IN INFECTIOUS DISEASES AND PUBLIC HEALTH, ALBANY MEDICAL COLLEGE, ALBANY, N. Y.

WHEN the New York State Department of Health was organized and established in its present form by the public health law enacted by the legislature of 1913, one of the first objectives set by Commissioner Biggs and the Public Health Council was the development of higher standards of training for local health officers, public health nurses, and other officials charged with the administration of the state health service.

The great increase of knowledge in recent years as to the modes of transmission of disease and the means of its prevention, had resulted in new views and new practices in the domain of preventive medicine and public health administration. Obviously, one of the first things to be done if the public health service of New York state was to be thoroughly modernized was to give local health officers and other health workers an opportunity to secure a systematic knowledge of the recent developments in the field of sanitary science. It was also important that they should obtain at once a thorough, practical understanding of the new state sanitary code which had been enacted by the Public Health Council in order to establish uniform and modern health regulations and practices throughout the state.

This need of promoting the instruction of health officers had been foreseen in the drafting of the new public health law which included a provision authorizing the Public Health Council to prescribe the qualifications of health officers and public health nurses, as well as of sanitary supervisors, directors of divisions, and other technical employees of the State Department of Health itself. The new law gave the State Depart-

ment of Health much more effective control over local health administration, but it was believed from the first that the best results would be secured not so much by direct intervention as by efforts to inform and assist the local health officers in the understanding and performance of

Council and of the Department since 1914.

Educational Requirements

As the first step toward advancing the educational standards of health officers, the Council accordingly enacted regulations to take effect November 1, 1916, prescribing the qualifications for health officers in New York state. These regulations as subsequently amended and now in effect require that local health officers shall have the following qualifications:

They shall be physicians and have complied with one of the following requirements:

(1) They shall have received the Degree of Doctor of Public Health in a course from an institution of learning recognized by the regents of the University of the State of New York; or

(2) They shall have received a certificate in public health from an institution of learning recognized by the regents of the University of the State of New York; or

(3) They shall have taken a correspondence course in public health of one year with at least one week of practical demonstrations in laboratory and field work, both correspond-

ence course and demonstrations to be approved by the Public Health Council; or

(4) They shall have taken a course in public health covering a period of at least eight weeks of which not less than twenty days, not necessarily consecutive, of five hours each, shall include instruction at an educational institution, or under the auspices of the State Department of Health in practical laboratory and field work with lectures and prescribed reading, such course to be approved by the Public Health Council; or

(5) They shall have submitted evidence satisfactory to the Public Health Council of special training or practical experience in public health work, with examination if required by the Council.

There is a further provision that

The New Health Viewpoint

HEALTH education for health workers as for the masses must be a continuous process. Standards are being constantly raised, and no system of health administration can be considered as completed and unimprovable.

Unpreparedness here is a costly error. The varied and extensive special knowledge of official, nurse, or sanitarian must nowadays be supplemented by the trained faculty of unifying local health factors into a related whole which makes preventive methods practicable.

Chance cannot be depended upon to develop the up-to-date executive. He is the product of a consistently thought-out program.

their duties. Most of these men were busy, practising physicians who had enjoyed but little opportunity to undertake post-graduate work in the larger medical centers, and so keep up with the progress of sanitary science. It would have been impracticable, indeed impossible, to establish ideal educational qualifications to be enforced over night among these health officers. The expedient and sensible course was to give these men every possible facility for increasing their knowledge without seriously interrupting their work, and at the same time gradually to raise the educational requirements through a period of years. This has been the consistent aim of the Public Health

under special conditions set forth in writing by the local board of health or other appointing power, or by the proposed health officer, these requirements may be waived by the Public Health Council. Experience has shown that without such a provision for exemption from qualifications it would sometimes be impossible to appoint any health officer in a community served by only one physician.

Health Officers' Instruction

Having thus laid down educational requirements for health officers the next step was to offer new educational opportunities to these busy men. To this end the Public Health Council as an emergency measure induced several of the medical schools in New York state to provide short courses of instruction for health officers. By 1915 such courses had been established in Albany with the cooperation of the Albany Medical College, in Syracuse with the Medical College of Syracuse University, in New York City with the University and Bellevue Medical College, and in Buffalo with Buffalo Medical College. In arranging these courses it was always held in mind that the health officers were in the main part-time officials, usually engaged in the practice of medicine in their communities; consequently every possible effort was made to conserve their time and keep down the expense. This was done by extending the course over a considerable period of time, and limiting the attendance to two days a week. A single experiment in giving a straight six weeks' residence course was not repeated because it was never again possible to interest a sufficient number of health officers. This conclusively demonstrated the necessity of the other plan.

Courses organized in this manner have been given at these four medical centers at intervals since 1914. In addition it was found desirable to organize correspondence courses for health officers who lived so far away from the cities mentioned as to make attendance at a "residence" course impracticable. One such correspondence course was started at Albany and another in New York City, in cooperation with the University and Bellevue Medical College. The latter course has been especially successful, and has been given continuously since 1915. A student may matriculate and commence this course at any time. It includes one year's reading course with frequent examinations supplemented by one week of resident instruction and field work. Health

officers to the number of 255 have received certificates in this course and fifty-seven are now taking it.

In all the courses a thorough study is made of the public health law and special emphasis is laid upon the administrative features of the state sanitary code. Demonstrations of the various modern laboratory tests are given with a view to making clear their value and their limitations. This is considered necessary because many of the health officers are physicians who, although good clinicians, were graduated before the science of bacteriology had reached its present state of development. In fact, at the time when many of the present health officers attended medical schools there was little or no opportunity for them to obtain any training in preventive medicine. As an example of the eagerness with which men of this type have taken advantage of the special courses offered by the Department it may be mentioned that out of a class of fifty who recently completed the course at Albany, four of the members who received a mark of 100 on the final examination had been graduated for thirty years or more, and a fifth had been seven years out of medical school.

A Typical Course

A more concrete idea of the character of these courses may be obtained from the announcement of the course as recently given by New York University. Although primarily intended for health officers, this is open to any qualified person interested in public health problems. The work is divided into fall and spring semesters with an interval of three months during the winter to accommodate health officers in rural districts, for whom traveling is difficult at this time. The course covers the work of the health officer in all the usual phases of preventive medicine, both technical and administrative. The required textbooks, which include the well-known standard works of Park, Rosenau, Chapin, Mac Nutt and other authorities, are supplied to enrolled students at 25 per cent discount. The fees include a matriculation fee of five dollars for those not previously matriculated at the University, and a tuition fee of twenty-five dollars. Students of previous years in any of the public health courses are invited to attend as many sessions as possible without additional charge, and this privilege is often used. Certificates are given to those who upon examination, successfully complete the course. The following random selections from

the twenty-four days program indicate the nature of the instruction given:

- Introductory lecture.
- Lecture and demonstration of general bacteriology and technic.
- Symptomatology, epidemiology, and control of the enteric diseases.
- Milk and milk products, production, pasteurization, etc.
- Diphtheria; laboratory diagnosis; the Schick test; antitoxin.
- Child hygiene, prenatal care, infant care, care of pre-school child, school child.
- Tuberculosis: Early diagnosis, treatment and control.
- Manufacture and use of smallpox virus and rabies virus.
- Smallpox: Differential diagnosis, epidemiology, etc.
- Diseases of adult life.
- Duties of health officer with the insane.
- Rural Hygiene.
- Industrial Hygiene.
- Routine duties of a health officer.
- Hospital management of communicable diseases; disinfection.
- Parasitology of the blood and the intestinal tract.
- Epidemiology.
- Vital Statistics.

Appraisal of Results

The response to the action of the Department in offering these courses has been most gratifying; and the public health training of a majority of health officers of the state is without question substantially better today than it was eight years ago. During these years a total of 458 health officers have completed either the residence or correspondence course, while in addition ninety men have taken the course in more than one year, making a total of 548 health officers, who have completed the instruction. At the present time ninety-six health officers and other physicians are actually taking the course, or are enrolled. By way of comparison, it may be mentioned that the total number of local health officers in the state is now 966, these men covering 1,466 local health districts.

It is clearly evident from the statements of those who have taken these courses that they feel that they have been distinctly benefited not only in connection with their public health duties but in their general practice of medicine. The Department believes that the cause of public health is also advanced when men in general practice take this opportunity to gain a broader view of preventive medicine, even when they are not health officers, and each year an effort is made to enroll students from this group.

Instruction for Nurses

Another noteworthy forward step which dates—(Continued on Page 741)

The Fat-Soluble Vitamin In Relation to Health

By H. C. SHERMAN, PROFESSOR OF FOOD CHEMISTRY, COLUMBIA UNIVERSITY, NEW YORK CITY.

THE existence of a fat-soluble substance or substance essential to the normal functioning of the body was established independently in 1913 by McCollum and Davis¹ and Osborne and Mendel^{2,3} through experiments in which it was found that young animals on food mixtures alike in all other respects would continue to grow and thrive or would soon stop growing and shortly thereafter die, according as the fat in those food mixtures was butterfat or lard.

At the same time, Osborne and Mendel recorded³ the fact that animals suffering from lack of this fat-soluble substance became subject to an eye disease which has since played an important part in the study of this dietary deficiency and is variously designated in different writings as ophthalmia, xerophthalmia, keratomalacia, and conjunctivitis. Both because an infection is involved here and because the characteristic susceptibility to this eye disease is accompanied by an increased susceptibility to other diseases also, the pathological effects of this dietary deficiency are less clearcut than those of either vitamin B or vitamin C. Since, however, in the case of each vitamin the characterization of the substance depends as yet chiefly upon the physiological or pathological effects observed to follow the use of a diet deficient in the vitamin in question, it seems necessary to attempt to summarize the results which have been observed to follow the use of a diet deficient in fat-soluble vitamin. These observations have been made chiefly upon rats, not as is sometimes supposed because the rat is particularly susceptible to the lack of this vitamin, for as a matter of fact both rabbits and chickens have been found^{4,5} to need relatively more of it than does the rat, but because at the time of the discovery of this vitamin the rat had already become well established as the most practicable laboratory animal for feeding experiments for which he is suitable. There is no reason to doubt, and ample reason to believe that the omnivorous rat is a good representative of mammals generally, including man, in his need for fat-soluble vitamin and in

the effects which follow the use of diets which lack it or are too poor in it for the support of optimum nutrition and health. That similar results follow the lack of fat-soluble vitamin in the food, has been shown experimentally for species varying as widely as the fowl^{6,7}, the rabbit^{7,8}, the dog⁹, and the pig⁹, and there is much clinical evidence showing that the same is true of the human species^{10,11,12,13,14,15,16}. According to McCollum¹¹: "There are several instances of the occurrence of conditions described in the literature as xerophthalmia, which seem to be beyond question cases in which the disease has occurred in man as the result of specific starvation for the dietary essential, fat-soluble A." The records particularly referred to are those of Mori¹⁰ in Japan, whose cases of xerophthalmia occurring among children at a time of food shortage could be cured by feeding chicken livers (liver being rich in fat-soluble vitamin) and those of Bloch¹², whose cases among the children of the Danish poor also responded to the feeding of foods rich in vitamin A. Wells¹³ found in Roumania, and Dalyell¹⁴ in Vienna, cases of children suffering from eye trouble which was cured by cod-liver oil and most probably arose from deficiency of fat-soluble vitamin in their food. The xerophthalmia observed by Bloch¹² among Danish children was regarded as one phase of their condition of malnutrition. Here the eye disease was quite definitely related to deficiency of vitamin A in the diet since it was cured by feeding whole milk or cod-liver oil, and in 1918 the disease nearly disappeared from the community upon the general introduction, by government action, of butter into the dietary of the poorer people. Bloch studied the seasonal incidence of the disease and found it to be most prevalent in the season of most rapid growth. This he construes as further evidence that the eye trouble arose from shortage of a substance essential to growth, the shortage and therefore the incidence of the disease being most severe during that part of the year in which the demands of growth are greatest. Bloch also suggested that vitamin A may be neces-

sary for the formation of antibodies against infection and may be continually used up in this way as well as in growth.

Space is not available for a fuller discussion here of the evidence of diseases arising from shortage of fat-soluble vitamin in widely separated species including man. The reader who desires more detail will find it in the publications above referred to. In our judgment there is no room for doubt that animals generally, including man, need fat-soluble vitamin quite as much as do rats, and that the rat is both a practicable and a representative animal with which to study this nutritional need.

We shall therefore continue to draw experimental evidence regarding the physiological significance of the fat-soluble vitamin chiefly from work with the rat, confident that the same or similar effects will result in man also from the use of diets unduly poor in this vitamin.

Effects of diet deficient in fat-soluble vitamin.—When a diet lacking fat-soluble vitamin but adequate in other respects is given to a young growing rat, growth continues for a longer or shorter time according as the animal has a larger or smaller store of this vitamin in his body at the beginning of such an experiment. After growth ceases the animal may or may not remain at stationary weight for a time, then there usually sets in a loss of weight and a condition of general decline accompanied by increased susceptibility to bacterial infection. This lowered resistance results in a large proportion of the experimental animals developing the characteristic disease of the eye^{3,17} and it has been repeatedly found that diet poor in fat-soluble vitamin leads to weakness in other respects as well as to this increased susceptibility to eye disease. Osborne and Mendel¹⁷ report diarrhea and diminished appetite as frequently resulting from food poor in fat-soluble vitamin; and they have definitely correlated this deficiency with the occurrence of phosphatic renal calculi (bladder stones) among their experimental animals.¹⁸ The formation of these bladder stones they attribute to abnormal reaction

arising from local infection to which the lining membrane becomes susceptible as the result of the fat-soluble vitamin deficiency. McCollum and Davis^{1, 19} and also Drummond²⁰ report increased susceptibility to other infections including lung disease among individuals whose diet is poor in this vitamin. Steenbock, Sell, and Buell²¹ confirm this and emphasize also the susceptibility to bronchial troubles and abnormalities of the skin. In this connection they have written^{21, p. 92}:

In addition to the inflammation of the eyes, we have observed in many animals, large and small, an apparent resistance to infection of the eyes even though continually exposed by contact to severely infected animals, all on a fat-soluble vitamin-free ration . . . Many of these individuals succumb to respiratory infections, in fact we have been led to think that possibly a certain immunity to infection of the eyes is thus conferred. The incidence of respiratory infections as part of the syndrome induced by fat-soluble vitamin deficiency was described by McCollum in his early work. It may consist, as we have observed, of a nasal or bronchial catarrh or pulmonary infection with mucous or purulent exudate, at times even resulting in hemorrhage. Animals thus afflicted in the early stages of the disease sneeze and cough violently but later as the inflammation becomes confined more to the lungs the cough subsides and dyspnea becomes very pronounced with the slightest activity. Such animals fail very rapidly and even with the introduction of fat-soluble vitamin into the ration rarely show normal growth subsequently. A fat-soluble vitamin deficiency is also far from being conducive to normal cutaneous nutrition so that very often . . . evidence of dermal malnutrition makes its appearance. The fur appears bushy and thin, cutaneous growths occur on the tail, ears and nose, and finally sores, which heal with difficulty, appear on the feet, limbs, and body; all bear testimony to this state of malnutrition.

In subsequent work²² Steenbock and his associates have correlated still further the occurrence of respiratory disease with deficiency of fat-soluble vitamin in the food.

Quantitative investigations at Columbia University are showing²³ that animals whose diet has been relatively poor in vitamin A actually contain less of this vitamin in their lung tissues than do those whose food has furnished the vitamin in more liberal amounts.

Evans and Bishop²⁴ found that diets containing enough fat-soluble vitamin for growth and protection from eye disease may still require enrichment with this vitamin in order to enable the animal to meet the added demands of reproduction.

With so much direct experimental evidence of widespread weakening of the body when the intake of fat-soluble vitamin is low, it is not surprising that this dietary deficiency should have been assigned as a contributing factor in such diverse diseases as rickets, tuberculosis and pellagra.

In the case of rickets investigation has been especially active and has led to the discovery that the substance by virtue of which codliver oil prevents or cures rickets, while it is fat-soluble and is regarded by most writers as probably of the nature of a vitamin, is not identical with vitamin A; for codliver oil can be oxidized until its vitamin A is destroyed, as shown by the fact that it will no longer cure xerophthalmia, and yet the substance which prevents and cures rickets still remains. Recent contributions to the study of rickets and of the antirachitic substance are so numerous that to cite them individually here is quite impracticable. Reference is therefore made to the comprehensive review by Park²⁵ which includes an extended bibliography. Thus the study of rickets has both developed and subdivided the concept of fat-soluble vitamin with the result of setting off an "antirachitic substance" from the "antiophthalmic substance" with which the term "vitamin A" had come to be regarded as synonymous.

Whether the antirachitic substance is a vitamin in the sense that it is a normal constituent of foods and an essential factor in normal nutrition, or should rather be regarded as a pharmacological agent concerned not with normal nutrition but specifically with the pathological condition which exists in rickets, is still an open question. The fact that the subject is under active investigation at the present moment, so that any attempt to summarize the evidence might be rendered obsolete any day, makes it seem best not to pursue this point further at the present time. The recent literature of rickets is so voluminous and records so many important advances in our knowledge of the disease that it might well form the subject of a separate paper.

Reference should also be made here to the interesting observations of Hart, Steenbock, and their colleagues indicating a favorable influence exerted by fresh green foods upon the economy of calcium in the animal body^{26, 27, 28}. This they attribute to the presence in the green food of fat-soluble vitamin and the beneficial effect of this vitamin upon the effi-

ciency with which the body can make use of the calcium which it receives. The effects are particularly noteworthy in the maternal organism which is subjected to the relatively heavy demands involved in the nutrition of the fetus and the production of milk. From statistical studies Abels²⁹ has also concluded that fat-soluble vitamin is of special importance in the growth of the human fetus and the proper development of the mother.

The likelihood of serious depletion of the mother's store of vitamin A through the extra demands of pregnancy and lactation, and the greater incidence of pellagra among those women who are undergoing or have recently undergone this strain, is one of the reasons for suspecting that a low vitamin A content in the food is a factor in susceptibility to this disease. This might readily be true even if pellagra be found to involve infection by a definite organism as Jobling and Arnold have recently made probable³⁰.

While it would lead too far afield to enter here upon a discussion of the relations of food supply and nutrition to the incidence of tuberculosis and pellagra, it seems well to mention the suggestion which McCollum has so frequently emphasized, that dietaries poor in vitamin A are unfortunately rather frequent throughout America and Europe and that people weakened by such diet are more readily attacked by the diseases to which they are chiefly exposed in the locality in which they live, whether this be tuberculosis, pellagra, or some other disease³¹.

Certain it is that the foods which have been found by long experience to be especially beneficial in feeding both for the prevention and cure of tuberculosis are milk and eggs, both of which are rich in fat-soluble vitamin. There also seems to be, in the otherwise somewhat conflicting conclusions reached by different students of pellagra, a fair agreement on the fact that inadequate milk supply is closely correlated with occurrence of pellagra in the regions in which it is prevalent, and that liberal use of milk in the diet is especially efficient in the prevention and cure of the disease.

A liberal allowance of fat-soluble vitamin certainly makes for a higher degree of health and vigor. In experiments which are now approaching completion in the writer's laboratory³², two groups of rats of identical family histories have been kept under conditions alike in other respects but with dif.—(Continued on Page 744)

Recent Advances in Physical Education

Moral Ideals Are the More Readily Translated Into Right Behavior When Through Consistent Training the Healthy Body Becomes the Willing Servant of a Healthy Mind

BY M. G. BRUMBAUGH, NATIONAL PHYSICAL EDUCATION SERVICE, WASHINGTON, D. C.

WHEN I was a pupil in a public school my teacher did not know what to do with my body. It was definitely in the way. It interfered with the task the school was supposed to do. Could I have in some way checked my body in the ante-room or cloak-room and gone only with my mind into the school-room, I think my teacher would have welcomed me with a distinct sense of relief, for my body was his *bête noir*. It did not behave as he wished. He punished it, made it stand in corners with face to the wall, laid the rod of correction rather vigorously upon it, and in numerous ways made it unwelcome.

All this is changed. The whole boy is now welcomed in school. His body is no longer to be "kept under" but educated and fitted by systematic habits to be the ready and willing servant of the mind. It was held by the Greek schoolmaster that a healthy body is a willing servant, while a weak body is a cruel tyrant. To make strong, healthy bodies the Greek boy went as regularly and as long to the gymnast as to the tutor.

St. Jerome in his letters on the right education of a young woman said to her mother, "I would have your daughter so educated that having a body she should not know it." This sums up not only the moral but the physical aim of education.

When the world-war came to us and our boys between twenty-one and thirty-one were called to the colors, we were appraised suddenly of the very great need of a sound and universal system of physical education. The rejects because of physical defects will always remain as an indictment against a school system that failed to conserve or advance the physical vigor of the race. Competent authority asserts that fully three-fourths of our school population suffer from some physical defect.

To detect these defects, to remedy

them, to conserve the increment of health that is brought to the school, and to set up a systematic and rational system of training that will establish health habits, these are the aims and needs of the wiser educational activities of the day. The essential need for this was not created but revealed by the world-war statistics.

In our larger cities, where opportunities for bodily exercises and health-producing activities are most restricted, departments of physical education have been established. The results have been most pronounced. Attendance has been increased. Study has been made more easy. Discipline of a corrective nature has been reduced in large degree. Intellectual progress has been promoted in a definite way. Moral ideals have been translated more readily into right behavior.

In Philadelphia, where in 1908 physical education was introduced in all the public schools, the intellectual average of all pupils was, in one year, advanced almost nine per cent. In other words, there was a great gulf between teacher and pupil, a gulf of physical defects, and not mental inferiority. When these physical defects were removed the pupils' mentality was reached and the succeeding gain in the intellectual life of the city readily achieved. This has been confirmed in many urban school districts. It most definitely establishes two facts of great value to educators and to parents: (1) that many so-called mental defectives are not in any sense mentally defective. They simply suffer from physical impediments of one sort or another, most of which are subject to correction under proper and competent diagnosis and treatment. It is manifest that for many reasons the earlier in the life of the child these physical limitations are removed, the easier the task, the better the status of the race; (2) that sound physical condition is essential

to right intellectual development.

The National Physical Education Service at Washington has set itself the altruistic aim of universal right physical training in all the schools of the republic. It has wisely sensed the fact that this matter is a national concern quite as much as it is a local concern. To give emphasis and meaning to its aims, this service has promoted in Congress an Act known as the Fess-Capper Bill, the aim of which is that in all the states the physical welfare of the child shall be as carefully conserved as its mental progress. Federal aid logically follows as an aid to the states in quickly carrying into operation, wholly under State control and direction, a system of universal physical training, and provides that this aid shall be used only to train teachers and to compensate teachers. Thus the nation emphasizes the fact that the trained teacher is the paramount need of the schools.

This service has also stimulated wise citizens in the several states to secure legislative enactments to conserve and promote universal physical and health training in all the schools. Pending final action by Congress, which action will surely be had at the next session of Congress, the importance of this service has been recognized by the enactment of laws for universal physical education in at least thirty-two states. Others will likely follow this splendid example.

It is a source of satisfaction to the friends of the republic to note that at least one great political party has definitely declared in favor of National Physical Education with Federal aid. All the great organizations of forward-looking and unselfish citizens have endorsed the movement and are aligned with its active supporters. The great women's organizations, the teachers of the Republic, the Rotary, Kiwanis, Lions and related groups, and the American Legion are all solidly supporting the movement. It may well be that in

the next advance the Legion, whose members saved the republic from its foreign foe, may lead in the campaign to save the Republic from its internal foes—disease and ignorance, and the almost endless line of foes that troop under the sooty flags of disease, ignorance and neglect.

More significant perhaps than this is the action of the Secretary of War in calling to Washington in November 1922 a large group of leading citizens from all parts of the republic to consider the necessary steps to be taken to remedy existing physical defects of our citizenry and to plan a nation-wide physical education service. The needs of the nation led to this great conference. Its findings are

now with the President. Undoubtedly when Congress convenes, the Chief Executive will have practical and pertinent advice to lay before our National Legislators.

Even more significant, it seems to me, is the nation-wide interest taken in this movement by leading individuals. One cannot in this space name any of these. But in press, pulpit, forum, and friendly conference the fact is proclaimed that if we are to be mentally and morally the people we long to be, we must lay the basis for all sound intellectual advance and all sane moral guidance firmly and surely in the physical sanity and wholeness of our entire population.

Red Cross Dental Clinic

A DENTAL clinic for children, manned by a voluntary staff of dentists, was opened in the Children's Hospital, Portland, Me., in May, 1918. Located in the hospital building and sponsored by the hospital authorities, it was carried on for two years, or until May, 1920, at which time the operation of the clinic was taken over by the local chapter of the Red Cross.

Under this new régime a full time dentist was employed. Nurses from the various hospitals in the city act as assistants serving for a period of weeks, the district nurses do the follow up work in the city, and two local dentists give their time part of one afternoon each week to the extracting clinic.

The clinic rooms are on the first floor of the Children's Hospital. They include a well lighted and equipped room containing two dental chairs. At one end of this room is a small extracting room and off the other end of the main room across a small hall, is the office of the director. The clinic is open every week day from nine till twelve with the addition of Saturday afternoon. All patients must be recommended for treatment by some person to whom this privilege has been granted. Since the clinic is practically free, a five cent fee being charged for each visit, application cards are given out only to those who will see that the privilege of dental care at this price will not be abused. In practice the district nurses make practically all investigations and recommendations for admission for treatment. They are the "feeders" for the Red Cross Dental Clinic.

The application for enrollment in the clinic card reads:

I (parent or guardian) hereby apply for registration and authorize treatment and if necessary the administration of a general or local anesthetic for . . (child's name) . . and agree

View of the Red Cross Dental Clinic for Children at Portland, Me. The doorway visible at the right opens into the extracting room.

to fulfill the requirements of *keeping the teeth clean—and to return for treatment periodically as required.*

On the reverse of this card are blanks for recording facts relating to the family. With this card signed and the young patient admitted and a case card filled out visits are made only by appointment. Those who persistently break appointments are barred from the clinic. There is always a long waiting list, far more than the operator can care for, and

there is no need to go into the highway and search for patients. Sometimes the parents send children to the clinic, who never arrive, perhaps a movie appealed more strongly. In such cases the father has been known to have used the old fashioned treatment for the child and the child has been allowed to return to the clinic, but, when neither parent nor child is interested, that opportunity is given to the one next on the waiting list. There were on this list approximately 450 names in March, 1923.

During the year ending March 31, 1923, the records show 3,856 visits made by the 1,811 children enrolled at the clinic. Fillings for the year total 3,526 and all other operations 3,542. In his annual report to the Red Cross, Dr. Horatio C. Meriam, director of the clinic, says, "These figures show some variations from those of last year. The number of completed cases has taken a big jump. The waiting list grows, and it is unfortunate that we are unable to take care of more children, as some of these children have been waiting nearly a year . . . The falling off in the number of fillings and extractions is undoubtedly due to the policy started a year ago of confining our work chiefly to children under ten years. The number of six year molars extracted this year is about two hundred less than a year ago, which shows that the efforts made toward the preservation of this important tooth are bearing fruit."

On entering the clinic one sees in the hall a fare box, that piece of mechanism more frequently encountered on entering a street car. This is loaned to the clinic by the local street car company and in it each patient is supposed to deposit five cents each time that a call is made at the clinic. Of course this rule is not without exceptions and no child is turned away even if the nickel is missing.

The experience of this clinic has again demonstrated that the volunteer staff is not the best way to secure results. With sufficient volunteers recruited to adequately cover the field, their number gradually dwindles and only the few faithful ones remain. It is hoped that the Portland Red Cross Dental Clinic will soon be able to add another full time dentist to the staff. Yet with a limited number of workers it offers today the only opportunity in the city for dental care of children whose parents are unable to meet the financial burden of the private dentist's fees.

The Sanitary District of Chicago

Sewage Problems Grow with the Growth of a City Requiring New Installations at Least Every Ten Years. Chicago's Problem is International.

By LANGDON PEARSE, SANITARY ENGINEER, THE SANITARY DISTRICT OF CHICAGO, CHICAGO, ILL.

IN THE thirty-four odd years since its organization, the Sanitary District of Chicago has built the main drainage channel from the Chicago River to Lockport, which reversed the flow of the Chicago River, and also the two collateral channels, the North Shore and the Calumet. As a result, the sewage has been removed from the entire lake front of Cook County, some thirty-four miles long. The Chicago River has also been

widened and straightened and obstructions removed, and new bridges built so as to make a channel with a minimum width of two hundred feet between dock lines. Further, a power house has been built at Lockport, on a fall of thirty-four feet, to recover the power running to waste, whereby electric power is generated to light the streets and parks of Chicago, run the sewage pumping stations and treatment works and other municipal utilities. This power is a by-product solely, as the primary object of the main channel was the reversal of the Chicago River and the disposal of the sewage of the Sanitary District by dilution.

The charter of the district provides for the dilution of the sewage with a minimum ratio of 3 1-3 cu. ft. per sec. per 1,000 people. On this basis the capacity of the channel, namely, 10,000 cu. ft. per sec. would care for three million people. Owing to the steady growth of the city of Chicago

in amount of about seven hundred thousand people every ten years, and to the additional load produced by the big packinghouse industry, and the Corn Products factory at Argo, an additional load equal to over one and one-half million people has been placed upon the Main Channel over and above the wastes of human origin. Consequently, the capacity of the channel for dilution has been exhausted. For a number of years the

many years, that is, the amount of diversion from the lake. The canal was planned for a diversion of 10,000 second feet. A few weeks prior to the opening of the canal, authority was given to the Secretary of War to regulate navigable streams, and under this power a permit was issued to the Sanitary District for a flow of 4,167 cu. ft. per sec., a figure based solely upon the navigable velocities in the Chicago River, then a narrow and

crooked stream. Since that time, the Sanitary District has spent upwards of sixteen million dollars in widening and straightening the river and removing the obstructions. Believing that this work, in the aid of navigation, merited an increase in the diversion, various attempts have been made to secure an increase in the permit from the Secretary

TABLE I.—A GRAPHIC PICTURE OF THE REDUCTION IN THE TYPHOID DEATH RATE WHICH PARALLELS THE EFFORTS TO RENDER SAFE THE WATER SUPPLY.

trustees of the Sanitary District have recognized the need of supplementary methods of treatment to reduce the load upon the channel. In forwarding this program, intercepting sewers have been built, pumping stations erected and sewage treatment plants constructed and put in operation. By all this work, the typhoid fever death rate has been remarkably reduced and the water rendered comparatively safe. (Table I.)

A Discordant Note

In this program there has been one discordant feature which has worried the Board of Trustees for a great

of War, but without success. However, in order to comply with the requirements of the state law under which the district operates, the flow has been increased so that the present time about 8,500 second feet are flowed. Inasmuch as Mr. William H. Taft, when Secretary of War, had doubts as to the powers of the Secretary of War in the premises, a friendly suit was started to determine the rights of the Secretary of War in connection with the construction of the Calumet Sag Channel, which suit was later widened into injunction proceedings to determine the legality of the diversion, originally heard by

Judge Landis and then turned over to Judge Carpenter in the Federal Courts. A decision was recently rendered by Judge Carpenter, enjoining the District from taking more than 4,167 C.F.S., but the effect and operation of the injunction has been stayed by supersedeas during the pending of the appeal to and until the final decision of the Supreme Court of the United States. In the meantime, in order to work out a solution of the whole controversy, the Sanitary District has suggested that a bill be introduced in Congress to legalize the diversion of ten thousand second feet, and control the level of the Great Lakes by regulating works at the outlets of Lake Erie and Lake Ontario, and to construct supplementary sewage treatment works, so as to reduce the load in twenty-five years to one half the present load of human population upon the channel.

The agitation against the diversion of 10,000 C.F.S., is largely based upon the false premise that more water is diverted from Lake Michigan than should be permitted to conserve the best interests of the port cities around the Great Lakes and navigation. The facts of the case are that the lake levels are constantly fluctuating, in accordance with the laws of nature. Daily and seasonal fluctuations occur of far greater moment than any lowering of level ascribable to the Sanitary District diversion.

Reducing the diversion will not cure the difficulties which are claimed to occur. The only correct solution of the lake level problem is the regulation of the outflow to hold back the excess water in the Spring until Fall. This can be done for around two and one-half million dollars. The Sanitary District has offered to pay whatever the works may cost.

Present Program

The sewage treatment program now before the Sanitary District based on a diversion of 10,000 C.F.S., will require the expenditure of about \$100,000,000. Should the diversion be cut to 4,167 C.F.S., an additional expenditure of over \$25,000,000 will be needed for sewage treatment and upwards of \$100,000,000 for water purification. Thus an additional expenditure of \$125,000,000 will be en-

tailed, which will not help the lake level problem materially, whereas the expenditure of only \$25,000,000 in regulating works would do a real service and permit the lake levels to be effectively controlled.

With the facts before them it would be a simple matter for engineers to adjust the lake level problem in a short time, for the principles are entirely clear, but when it is necessary to harmonize the interests of the different states affected, as well as the Federal Government, the State of Illinois, the Canadian Government and others, not only state, but national and international policies are involved.

During all the discussion and litigation, the Sanitary District has been

ple. Other contracts will follow.

In the operation of the three treatment works the sewage of over 156,000 people is being actually handled today on a working basis. The activated sludge and sprinkling filter plants produce a high grade effluent in which fish can live, which requires no dilution. In addition from the activated sludge process, material is being recovered which is actually used for fertilizer by various agriculturists. This material contains about 5 per cent nitrogen on a dry basis. Growing tests made during the present season will give actual data from various localities on many crops, not only cotton, but peonies, roses and various kinds of vegetables. The park boards are trying the sludge on lawns. As a result an advance has been made in the sludge problem, because heretofore until the activated sludge process was developed, the sludge had such a low nitrogen content that it was movable with difficulty and was usually

TABLE II.—SEWAGE WORKS OF THE SANITARY DISTRICT OF CHICAGO.

West Side	1,430,000	Future.	Activated sludge.
Southwest	1,230,000	Distant future.	

steadily working on the problem of sewage treatment. The condition of the Illinois River demanded relief. In the sewage treatment program since 1909, two distinct lines of investigation have been followed, one on domestic sewage, the other on industrial wastes. Owing to the magnitude of the problem and the unusual character of the waste, experimental studies were carried on in four testing stations at a total expense of over five hundred thousand dollars to demonstrate how best to handle domestic sewage and packinghouse, tannery, and corn products wastes.

As the engineering studies developed, the division of the Sanitary District in seven major projects became evident, (Table II) together with a number of minor isolated plants for outlying villages where intercepting sewers would be too expensive at present. Of the projects the Des Plaines River and Calumet have been built and are in operation. A small plant at Morton Grove is also in service. The work on the North Side project is actively under way, the first contract having been let on August 9th, for approximately \$5,600,000 for a portion of the activated sludge plant to successfully handle eight hundred thousand peo-

dumped.

In the control of the plants, a staff of chemists and sanitary engineers are engaged, so that from the mass of data accumulated, each new plant can be improved. Sanitary surveys have been made of the Illinois River and its tributaries by the Sanitary District and recently for a year a joint survey was conducted with the U. S. Public Health Service. The results should add materially to the knowledge of the self-purification of streams.

Many of our citizens have supposed that the Main Drainage Channel solved forever the problem, but the old Main Channel is a machine, and like any other machine, living or inanimate, has a definite capacity for work. This capacity was exhausted several years ago, necessitating the construction of supplemental works. From the standpoint of the future, as long as Chicago continues to grow, there will be a sewage problem before it, necessitating every ten years the completion of additional facilities larger than are now required for the City of Baltimore or Milwaukee alone. That is the problem before the Board of Trustees of the Sanitary District of Chicago and the people of the Sanitary District.

State Institutions for Indigent Crippled Children

Describing the Minnesota Plan. Minnesota, Massachusetts, New York, Nebraska and Iowa Now Maintain Separate Institutions for Educating and Restoring Crippled and Deformed Children

BY CARL C. CHATTERTON, M.D., ST. PAUL, MINN.

MINNESOTA was the first state in the Union to appropriate money for the care of indigent crippled and deformed children. The exact date when interest was first manifested in the founding of the Minnesota State Hospital for Indigent Crippled and Deformed children will never be known. The first record of the need of such an institution is found in the proceedings of the fifth and sixth Minnesota Conference of Charities and Corrections. In the year 1896 Jessie Haskins, a slender crippled girl, properly instructed, read a paper before that body on the need of a state institution for the care of crippled and deformed children. The following year Dr. Arthur J. Gillette appeared before the body with a paper "The Duty of the State to Its Crippled and Deformed Children." The same year Jessie Haskins went before the state legislature to plead for the establishment of a state hospital and school in which crippled children like herself, whose parents were too poor to pay for treatment, might be cared for and educated. Her plea brought action largely because it was backed by an offer of free treatment professionally of all children who might come.

The offer was made by Dr. Arthur J. Gillette, and the same year a bill was introduced and passed which provided for the care of those who would come. Dr. Hastings H. Hart, who was then secretary of the State

Board of Charities and Corrections—now with the Russell Sage Foundation—gave his warm approval of the project.

This bill was not passed without some effort because at that time there was no such state institution or hospital for the care of indigent crippled and deformed children, nor was there a law in the United States—or in the world so far as we know—that could be used as a precedent, and the state legislature was loath to take up with a new and untried institution or system.

The bill had but one object in view, and that was the care, relief, and cure of the poor crippled children of the state of Minnesota, who, if they were not already so, would eventually become objects of local charity or wards of the state.

It was with surprise that the general legislature was informed that these children would be cared for free of charge by physicians and surgeons, and how well this has been done we must leave to your consideration.

Project Takes Form

On April 23, 1897, a law to provide for the care and treatment of Indigent Crippled and Deformed Children was approved and an appropriation of ten thousand dollars made. From this small beginning the state now has an institution of two hundred beds. The hospital grounds of twenty-three acres, a gift from the city

of St. Paul, adjoins a beautiful four hundred acre municipal park. The total cost to the state for buildings and equipment at Phalen Park approximates \$345,000. The institution is filled to capacity and has a waiting list of patients for admission. Two thousand eight hundred eighteen have been cared for in this hospital, and now one thousand nine hundred twenty-eight are under supervision in the out-patient department. The daily per capita cost averages about \$1.75.

The need of such an institution, I know, is apparent to every layman or physician whether he lives in the city or in a country community. City children receive, through free dispensaries, charitable institutions and visiting nurse associations, far better care than the indigent child in a country community. The crippled child in the country must receive his care through the county, charitable societies, parents, or friends and, recently, the county nurse. In many instances these sources of support have responded and the care so given to the child is commendable. The patient has often been sent to clinical centers where he could have the advantage of treatment by men trained in special lines of surgical practice, the county or friends paying the hospital and surgeon's fee as well. The country physician makes many visits and does his best as a general practi-

tioner, but often the child is some distance from him and home surroundings are anything but desirable for a cripple. Special apparatus is practically out of his reach. Good nursing, operative work, hygiene, and even nutritious food necessary for a favorable result in many cases is impossible.

Many physicians throughout our state have given freely of their time in caring for indigent children and many wonderful results accomplished even outside of a hospital. The greater number of cases, however, require hospital care and when our state institution was started there were few hospitals in Minnesota outside of the larger cities. In either case, whether the child comes from the city or the country, education of the crippled child is nearly impossible except through an institution where both the deformity and the disease is treated, and at the same time the child makes some progress in education and training.

State Care Preferable

The advantages of a state institution over a private institution are many. In its beginning the object of our state institution was to cure and educate and not to see how many could be cared for. No one individual has any advantage over another because he is placed there by a society, a corporation, or friends who contribute liberally to the institution. The waiting list is not transgressed because of solicitous friends. There is no political influence necessary in securing admission to the institution. No one is discharged except when there is no longer need of hospital treatment. Never has a case been turned away when there is further chance of improvement. Even when the result was most unpromising, the child has been taken care of until the end, because we felt we could better relieve his suffering than those at home.

Education of Crippled Children

Until very recent years the education of crippled children in the United States has been in the greater part sadly neglected. A crippled child is not a sick child and incapable of instruction, nor is he a normal child in whom strenuous exercise and hard work is a good medium of keeping him well. His place is between these two, and he will do best with quiet, restful, supporting measures, his mind occupied with tasks not too tedious which serve to make long hours pass more quickly but which in-

still knowledge which will be useful to him when he is ready to leave the institution and take his place among normal individuals.

Many of the children enter the state hospital when young, even before school age, and it is with these children that the good effects of institutional education must show. We expect these children to leave even better equipped than normal children, and to arrive at home able to carry on general school work with children of their own age and mental qualities.

Recent investigations at the State Hospital for Indigent Crippled and Deformed Children have shown us that crippled children, with few exceptions, passed with higher average than children of the same age attending public schools. That is, on an average, the crippled children were found to be from one to four years in advance of children of the same age under normal conditions. With the older children, who come in after they have had more or less training, the problem is more difficult. Imagine a boy or girl sixteen years of age who has never attended school, or one whose education has been only one or two years in public school, or whose entire training has come from mingling with other children in the home who attend school.

We, as orthopedic surgeons, know that in addition to restoring the limb or function we must, at the same time, insure that independence which will assure the patient of his own well being and blot out his dependence upon others. If educational and training methods are not used when the child has his medical and surgical care, then the greater part of our work is for naught and the child is hopelessly outclassed in mental, moral, and physical attainments, and he still remains a parasite upon society.

The average patient stays at the hospital nearly a year. The paralyzed or tuberculous case may stay five years. At present the discharge from the hospital depends only upon the surgical cure. However I am free to inform you that the time is not far distant when the discharge from the hospital will not depend entirely upon the surgical cure, but upon certain mental and moral requirements as well.

The hospital now offers what would correspond to the first eight grades of a common school. It is rare that one comes to the institution who has attained this grade, but if more advanced, provision is made for him. A cripple has greater need of a good

elementary education than a normal child, as the latter has greater opportunities of acquiring knowledge. He can run about and almost insensibly imbibe knowledge. The crippled child needs to have it brought to him. The principle of preliminary education should be thorough enough so that the child can take up some vocation, and in the end become self-supporting.

At the last legislature in Minnesota, a bill was presented and passed granting three hundred dollars a year for special instruction to any crippled child, provided at least five children in any given community received this instruction. This beginning can but stimulate the work in the public school and in special schools for crippled children and will be the means of support of a large school near the present hospital. A considerable sum of money has already been raised through private sources for the beginning of this school and we feel it will not be difficult to interest our legislators when they see the great good of special training that can be given to the physically handicapped.

Vocational Training

The cripple is barred from many lines of work, but in a large number of industries there are many branches that offer hope for those physically impaired. The vocational training offered at the state hospital is not unlike that offered in the average high school course, the object at the present being, not to train the child for any special line of work but to teach him to use his mind and body so that he will become self-reliant, self-thinking, and capable of accomplishing tasks by his own efforts.

The different kinds of work actually taught are many. A course in manual training, including actual labor in the instrument shop, carpenter work, gardening, basket-making, leather work, rug making, and many other arts are taught the boys. Dietetics, actual preparation of food used, sewing, fancy-work, home hygiene, and millinery are included in the work for girls. Some of the boys are very apt in needle-work and dietetics, and some of the girls excel in basket and rug-making. Stenography, bookkeeping, designing, and many other fields offer development for such children, but before we can offer these subjects we will need a larger corps of teachers, and materials, and more adequate room. The field seems almost unlimited, and we believe—(Continued on Page 748)

The Railway Accident Problem*

The Thirteen Million Licensed Automobiles That Share the Highway Privileges With the Railroads Must Render Cooperative Effort in Reducing the Death Rate From Crossing Accidents

BY CHARLES E. HILL, GENERAL SAFETY AGENT, NEW YORK CENTRAL LINES, NEW YORK CITY.

THE railway accident problem includes all the difficulties and perplexities that are encountered in the promulgation and execution of any efforts which have for their purpose the elimination or reduction of accidents. One of the outstanding problems of this country is the frequency of accidents. The fact that a life is snuffed out by accident in the United States every seven minutes should cause all red-blooded Americans to rise up as a unit and insist that this terrible sacrifice shall cease. Such needless wastes of human life is a challenge to intelligent citizenship, and it is particularly obnoxious to those who have a pride in their country's leadership among the civilized nations of the world.

The railroads are contributing so great a share of the toll of death and injury from accidents that they must not only do their part to relieve the distress and suffering which inevitably follows in the wake of accidents, but they must assume the leadership in the elimination of the large percentage of preventable accidents from their toll of casualties. The majority of our steam railroads are recognizing the situation and are ready and willing to assume their full duties in the premises.

What the Casualties Are

Without introducing elaborate statistics I want to call attention briefly to the record of the five years ending with 1921, which will indicate the magnitude of the problem with which we are confronted. In the five year period ending December 31, 1921, the total number of casualties on the railroads of the United States was 846,732 of which number 39,305 were deaths and 807,427 were injuries. The total number of casualties are made up of 12,780 employees killed and 715,222 injured; 1,479 passengers were killed, and 35,529 injured, and 25,046 other persons killed and 56,676 injured.

The casualties to employees con-

stitute approximately 85 per cent of the total number occurring on railroad property. These figures mean that one employee is killed every three and one-half hours and that one employee is either killed or injured every three and one-half minutes. Expressed another way it means that about one employee out of every fourteen is either killed or injured each year. These facts ought to be sufficient to insure the whole hearted support of every employee on the railroads of this country as they are the ones most vitally concerned. It is they who are contributing of their flesh and blood to the field of slaughter a substantial portion of the entire number resulting from railroad operation.

Fully cognizant of the enormous life wastage resulting from casualties to its employees in the United States each year the railroads of this country are at last realizing the seriousness of the problem. We must meet the issue squarely, analyze the causes of accidents and apply the remedy. Before any success along the lines of accident prevention can be expected there must be cooperation between the employer and employee. They must realize fully that the safety of life and limb is paramount to anything else and that both must at all times work together to the end that safety will become an integral part of railroad operation. Safety committees, usually composed of supervisory officials and employees in the rank, have a commanding position in this important field and opportunity to perform real services to their fellow employees is of incalculable value.

A good, live chairman surrounded with an active committee can reach out and come in contact with employees who need their suggestions or advice, either through lack of experience or by reason of their thoughtlessness and indifference, and can set them aright and put them on the path that will keep them from danger. Likewise, the committee can cover their entire territory with respect to its physical condition and

take such action as will bring about corrective measures. Too many safety committee meetings are held in a perfunctory manner. Also there seems to be a disposition to give the greater portion of the time to physical conditions rather than practices, whereas the latter cause produces the most of the accidents. This preoccupation with physical conditions is only natural because this was originally the greatest field for safety work in the correction of physical conditions. This field still exists, but not nearly to the extent it did several years ago.

Create Safe Habits

One of the greatest agencies by which accident prevention can be accomplished is through education. Education has much to do with the molding of the mind which is reflected in the daily life of the individual. Education teaches the safe way to do things. Its influence is continuous. The part it plays is of inestimable value. If a man always does that which he knows to be right, takes the course and follows the method he knows to be safe the problem now confronting us would not be so serious.

The human mind is subject to whims and is not too readily susceptible to reason. The characteristic reactions formed early are difficult to change. Habits formed in childhood tend to become fixed so that when the individual has reached mature years they are an integral part of his life and are practically unmodifiable.

This is the most difficult aspect of the accident situation. Science may develop means by which physical characteristics can be changed but no effective way has been found that will change the habitual reactions of the individual excepting by constant and persistent teaching. The remedy must be continuous and applied with fortitude and patience.

I have great faith in the future. I believe the system of education, the teaching of safety in the public schools as is now in vogue in several of the large cities will lay the founda-

*Condensed from an address before the third annual safety Supervisors' School of the Chicago Safety Council, Chicago, May 28, 1923.

tion for the men and women of the future so they will become imbued with the spirit of safety and make it a part of their ethical code. Great credit is due to those who have labored so earnestly to have safety become one of the fundamentals of our public school system.

There may be some who object to teaching the principals of evolution but no opposition arises to making safety a fundamental part of the basic knowledge that is to be acquired in our public schools, and we can expect as a result of such teaching that succeeding generations will show a gradual but positive improvement in the habits of the individual to the extent that accidents may become the exception rather than the rule. As a result of this process we will see in the future a reduction of casualties far beyond our expectations.

Safety Supervision

Supervision will accomplish results where education has not made its impression on the individual. It is rather an adjunct to education. Those who have to do with the supervision of men or those who are in direct charge of men have it within their power to practically eliminate the accidents from those under their care. A foreman, or one in a supervisory capacity in charge of men, has responsibilities and opportunities of tremendous importance. A good foreman is one who practices and preaches safety, one who instills the principles of safety in his men, one who is alert and observing of his employees in respect to safety.

To have the proper foreman, one who can and will prevent accidents and preserve his man-power; we must have at the head of the departments an official who is willing to give support. His influence for good or evil percolates through the various executives to the men immediately in charge of the class of men, the nature of whose work or the recklessness of whose habits substantially contributes to the increase of casualties. Safety must be made a part of the day's work. It must be instilled in the hearts and minds of those men who have to do with the supervision of men. These are the ones who hold a position of trust. These foremen should be trained in safety and should qualify in its application. The heads of departments have it within their power to see that such men as have been described and no others are in positions of that kind.

When the head of a department is

thoroughly in accord with safety and when he is lending his support to the movement in a wholehearted fashion his attitude will reflect in the men under his jurisdiction and so on down to the man in direct supervision of the employees. The spirit of safety is so manifested in those in direct charge of men and its influence is so great that the most skeptical are convinced of the benefits resulting from this influence.

It is difficult to leave this feature of the subject without laying particular emphasis on the importance of not only the support of the official but this support should be aggressive and with the same interest and zeal manifested in the conduct of any phase of railroad operation.

We must achieve the attitude that good railroading cannot be accomplished without the elimination of accidents. That it is as important to prevent injuries as it is to prevent damage to equipment or to other railroad property.

Nature provides a remedy for a number of physical ailments, it also applies punishment for the violation of its laws which is in the form of pain and suffering. The time may come when a remedy will have to be applied to aid in accident prevention. Many forms of disease that were at one time prevalent are no longer with us. The death rate in this country as a result of sickness has been materially reduced and longevity has been increased through scientific study and the application of the knowledge thereby acquired. We have already reached the point where illness is as a rule unnecessary and where men will continue as active at eighty years of age as they did two decades ago at the age of sixty years.

All of this has resulted from an application of the things gained from years of scientific study. Man has unconsciously disciplined himself. May it not be advisable for him to at once stop and take an inventory of his daily acts as they affect himself or his fellowmen? Railroad employees who are making safety a part of their work do not care to be associated with other employees who are habitually careless any more than they care to come into contact with a contagious disease or with the things that are likely to cause sickness. Those who are careless and thoughtless, for their own benefit as well as for the good of their fellow workers, may be aided in saving themselves and others by being held accountable for their acts causing or contributing to an injury or death.

Human Life Cheap

The time must come when accidents resulting in personal injury or death will be considered at least with equal importance to accidents resulting in damage to property. Officials and employees should recognize the fact that injury and death are not to be considered necessary or inevitable to railroad operation. Let those who are habitually careless realize that men of that type are a menace to themselves and others and are not desirable employees.

The time is already here when service and safety are synonymous in successful railroad operation. Both apply with equal force in the discharge of full duty to that great army of railroad employees as well as to the public at large.

Analysis of the causes of accidents precedes intelligent remedy. The number of casualties, particularly to employees during the five year period mentioned means little without an analysis of the causes leading up to these accidents. Statistics show that only about 2 per cent of the entire number of accidents to railroad employees are classed as unavoidable. This leaves 98 per cent of the entire number which should be subject to control. In making further study of this class of accidents we find that their causes are chargeable to two elements: (1) improper practices or methods of doing work, and (2) improper or unsafe physical conditions.

When organized safety work was inaugurated on the railroads twelve or fifteen years ago it was found that through the lack of any systematized effort a large percentage of our casualties were caused by defective machinery and improper conditions in the yards and at other places on the railroads. Since the physical situation on the railroads has undergone such a marked improvement we now find that about nine out of every ten casualties result from improper or unsafe practices and methods of doing the work.

Such a substantial portion of the number of casualties emphasizes the tremendous importance of this cause, nor are we to lose sight of the fact that even though accident may be chargeable to the unsafe manner in which the injured employee or one of his co-workers performed their work. Further analysis may disclose that failure to perform this work in a proper manner as directly due to the lack of supervision. This forcibly brings out the prime importance of educating—(Continued on Page 754)

Heating Systems for Mercantile Establishments

A Description of An Indirect System Recently Installed for the R. H. White Company, Boston, Mass.

By R. R. HAMMER, ASSISTANT ENGINEER, CHARLES H. TENNEY & Co., BOSTON, MASS.

THE following article is a description of a modern centralized heating and ventilating system such as is used in many large public buildings and department stores. A sectional diagram describes a typical system of this kind with centralized control which has recently been installed in the department store of R. H. White Company, Boston, supplanting an old indirect heating installation, Charles H. Tenney & Co., acting as engineers for the above installation.

In considering the heating and ventilating for a public building or department store wherever large areas are to be heated and at the same time supplied with fresh air, the greatest difficulty encountered has been the inability to procure a constant and reliable circulation of properly heated fresh air. In order to accomplish this, a variety of systems have been used from time to time with varying success. A former and very common method was in the use of indirect radiators set in the wall, and in consequence these radiators were extremely inaccessible in the event of repairs. These radiators in turn were connected to open air ducts or flues in back which allowed a free passage of air with its attending dust and bacteria to pass into the area to be heated and ventilated after having

passed through the radiator or heater coils located at the head of these various ducts. This type of system has proved itself very unsatisfactory for various reasons. Outside air enters these ducts or flues unrestricted as to velocity and is acted upon by changeable outside air direction.

Under these circumstances such ducts or flues soon become heavily coated with dust and dirt deposited from outside and, when favorable wind direction acts upon certain ducts of such a system, this dirt deposit is carried on through the radiator and heating coils and deposited throughout the area to be heated. It has, therefore, become necessary to develop a system whereby a continuous, reliable, and positive change of air of say from four to six times an hour could be attained in the entire area to be heated supplying clean, heated air and controlled from a central point.

Following is a brief description of a centralized heating and ventilating plant as installed in the R. H. White Company department store in Boston:

The modern inventions of the last century have exploited and utilized practically every force of nature for industrial purposes. One powerful agent, however, a force having tremendous industrial possibilities, has

been almost entirely neglected by managers, executives and engineers. This is moving air. Perhaps it has been due to our close, daily and intimate relationship with this ever present force and for this reason we have failed to realize its potentialities.

Practically every progressive, industrial institution can use moving air to a distinct profit and in the case of proper heating and ventilating increasing the efficiency and health of their workers.

In making this installation it was imperative to eliminate the use of any floor areas for installing heating coils or floor registers, and in consequence these ventilating and heating ducts were carried under the basement ceiling to points directly under the main floor wall show cases, and risers were erected in back of these wall cases which were in turn connected to horizontal ducts on the main floor and which were placed on top of and parallel with same. These in turn were pierced by grills or registers allowing a free passage of washed and heated air to pass into the area to be ventilated. These registers or grills were faced with wood to correspond with the same exterior finish as wall show cases below, and placed approximately eight feet from the floor. This prevents the warmed

Section diagram showing plan of centralized heating and ventilating system for use in stores and public buildings.

air from directly striking those passing underneath. The extreme simplicity of operation of an installation of this nature can readily be appreciated by the fact that all heating coils used in tempering the incoming air as well as the reheating coils used after this air has passed through the air washing fan are practically a self-contained unit which can be located in a comparatively small basement room or compartment where the same can be controlled from one point.

The air washing feature of the above described unit recirculates the water used for washing purposes which in turn is automatically controlled by a float, and the only additional water used is that lost through evaporation which is extremely small and is automatically supplied from city water connection.

It is also to be understood that in a self-contained air washing fan of this description the spray nozzles do not sufficiently break up this water to form a mist or act as a humidifier as is the case in some air washing systems. The spray falls upon a revolving bronze screen and the incoming air is forced to pass through this screen which in turn is being continuously covered by a heavy spray of water. In consequence, the air is cleared of dust and impurities and somewhat lowered in temperature before passing on into the distributing ducts. It will be readily seen that this system is thoroughly practical for use during the summer months as a means of supplying fresh air, and with its attending air washing and cooling feature a reduction of approximately from 4 degrees to 5 degrees F. can be attained without difficulty at the outlet grills. At the same time drafts and unpleasant air currents created by individual open windows or the use of fans, now so frequently employed, are entirely avoided.

Another extremely important feature in installations of this nature is the fact that a constant slight static pressure is produced throughout the area or room so ventilated which is sufficient to expel dead air through open windows and doors, at the same time greatly eliminating the entrance of cold air or drafts by the continuous opening of outer doors during the heating season as well as during summer conditions where changeable outside air currents are apt to sweep in large quantities of dust. This is especially true of department stores. The above fact has been proven quite

conclusively wherever a system of this nature has been installed. It eliminates to a great extent the dust deposit on merchandise and counters and in consequence has materially worked toward a better health condition especially among store employees, which in turn has a direct bearing upon a more efficient merchandising policy.

Considerable pioneer engineering has been necessary among executives and managers in order that a system of such vital importance should be more universally understood, and it is the author's belief that the older and cruder methods of ventilating and heating will soon be superseded by similar systems described herein, as installations of this kind have now been made with very satisfactory results in large department stores and public buildings in various sections of the country.

Social Legislation in North Carolina

Social legislation fared well at the hands of the General Assembly of 1923. No retrogressive step was taken in regard to North Carolina's social program.

Most important among the measures passed are the Mothers' Aid bill, the one to raise the age of consent from fourteen to sixteen years, and its companion making the legal age of marriage sixteen instead of fourteen, the establishment of an industrial training school for delinquent boys in eastern North Carolina and the bill to allow two or more counties to unite to build a county home. It was also favorable for the progress of public welfare work in North Carolina that the proposed amendment to the juvenile court law, which would reduce the age limit of jurisdiction of that court from sixteen to fourteen, failed to pass.

Prison reform bills sponsored by the N. C. Conference for Social Service traveled a rougher road than the rest of the social measures. Three out of seven bills on the program of the Conference introduced into the General Assembly passed. These were: to put the state prison on an appropriation basis; to abolish the department for criminal insane at the state prison; and to establish a colony for tuberculous prisoners. These last two were offered by Superintendent Pou and all three had his support. The bills which failed to pass were: to abolish flogging as a punishment; to reorganize the Board of Directors of the state prison; to

change the personnel of the Advisory Board of Parole; and to send all prisoners sentenced for more than three months to the state prison.

The appropriation to the State Board of Charities and Public Welfare was increased by the General Assembly from twenty thousand to thirty thousand dollars a year. The State Child Welfare Commission which has the enforcement of the child labor law in North Carolina received an annual increase of ten thousand dollars.

The Pencil Sucker

"Look at the boy."

"What is the boy doing?"

"He is trying to think."

"How do you know he is trying to think?"

"I know he is trying to think because he is sucking his pencil."

"Does he think he can get ideas out of it in that way?"

"No. He probably doesn't think about it at all. It is just a nasty and dangerous habit."

"Why is it a dangerous habit?"

"Because somebody with a disease may also have been trying to suck ideas out of the same pencil."

"I never thought of that."

"Yes. It's not thinking which causes many accidents, much suffering and many deaths. Whenever you see a pencil with tooth-marks on the end you will know that it has been used by somebody who doesn't think."

Financing Child Health Demonstration

Municipalities of less than thirty thousand population, and rural districts south of the Mason-Dixon line and east of the Mississippi are eligible for the second of three child health demonstrations being financed by the Commonwealth Fund. The communities interested should communicate at once with the Child Health Demonstration Committee, 370 Seventh Avenue, New York City.

Fourteen colored graduate nurses are now serving in the public health field in Alabama.

The International Association of Street Sanitation Officials will hold its next annual conference in Chicago, September 27 and 28, with headquarters at Hotel La Salle.

The Endicott-Johnson Shoe Corporation, Binghamton, N. Y., spent \$615,000 for the 1923 vacations of its fourteen thousand employees.

Three New Services of Life Insurance to Public Health*

By H. W. HILL, M.D., D.P.H., L.M.C.C., DEAN, FACULTY OF PUBLIC HEALTH, UNIVERSITY OF WESTERN ONTARIO, LONDON, CANADA.

LIFE insurance is the public health of economics. Insurance is, in economic welfare, just what public health is in physical welfare; for public health is, in the every day physical activities of men, the great foresighted, forehanded preventive against physical disaster; and life insurance is, in the everyday financial activities of men, the same foresighted, forehanded preventive against financial disaster. Life, accident and sickness insurance are even more evidently connected with public health than is insurance in general for they deal directly with the same problems of disease and death as public health. Public health is designed to prevent disease and delay death by physical measures. Life insurance, when public health fails, steps in, to prevent by financial measures, the losses and sorrow thus occasioned. The longer that death is delayed and the more that disease is prevented by public health, the less is the outgo of insurance moneys and the greater its income. Public health success thus permits cheaper life insurance; which in turn mean that more persons may become financially protected; and thus both insurance and the public are benefited, physically and financially, directly and indirectly. Since public health so greatly aids life insurance, life insurance should as greatly aid public health; for from no source can more help for either be obtained than from the other.

A Great Triumvirate

Medicine, public health and life insurance constitute a great triumvirate. Three well known professions are peculiarly interested in the prevention of disease, in the promotion of health, in the attainment of "a

good old age." These three are medicine, life insurance, and public health. How and why? Obviously this is true of the physician, for dead patients certainly are of no value to him. Restoration to health is his business, and prevention of disease rather than the cure, of the sick is constant-

Life insurance touches death and disease, not merely to meet the physical needs of the moment, as the physician does at a price, however just that price is; but to meet the financial needs of the moment associated with death and disease. It is true that this is also done at a price—but at a price that is paid long beforehand, during health and prosperity; not as the physician's fees are, at the moment when both health and prosperity are at low ebb. The physician may bring physical aid, may prevent physical death, and thus make future health and prosperity possible; but insurance brings financial aid at once, relieving the immediate situation; and provides, through the financial aid, that very physical aid of the physician which may re-establish the physical future as well as the financial. All the real interests of insurance, like the real interests of the physician, lie, but even more strongly if possible, in securing both life and health than in relief, either physical or financial; for the long life and prosperity of their clients insure to both of them the best chances of the best financial returns. Moreover, the longer the life of the policyholder and the greater his

health, the less is the expense to insurance, and the less to the policyholder also. It is cheaper for him (and cheaper for the community) that he be in health, at least alive, than be sick or dead. Health and long life mean greater savings to policyholders and make them better able to pay for all services rendered, including those of public health; and hence public health works out as the best policy financially for all three professions, while for the public itself, this combination yields the greatest of all returns, life. Now it is not by any means true of all commercial en-

ly looming larger and larger in the medical mind, because of its physical advantages to the race, and also because of its financial advantages to the physician himself.
Public health is well known as a development of medicine largely pushed by medical men, quite unselfishly, before these developments were foreseen. It is eminently fair and proper that the profession which first developed this science should reap some of the quite unforeseen but now obvious rewards.

Life insurance is the one sound, economic basis for physical welfare.

*Presented before the Life Underwriters of Ontario, London, Canada, February 13, 1923. 13, 1923.

terprises that everyone in it is benefited in all directions; and the consumer most of all!

The Public are ready to join the triumvirate. Thus life insurance, medicine, public health and the public form a natural union for prolonging life and health in the race. The interests of all four are identical; their operations should be conducted together. All four see the needs intimately and personally, although from different angles. The cooperation of each helps the other, directly and indirectly. The public, long hammered at by pamphlets, lectures, newspaper articles, immensely impressed by the triumphs of medicine and public health in the Great War, are ripe for big public health advances. These four then should co-operate more closely than at present. So far, life insurance has first recognized, not only the humanitarian aspect, but also the *economic* advantages of public health; and of the three professions it has most definitely set out to promote public health clearly and frankly as a big business proposition. This is too well known to require expansion here. It is time that public health and the physician should see how much life insurance can help them to attain their professional aims, and to do this on a sound economic foundation. It is time also to take the public into the combination, as one of the "firm."

There are three definite ways in which life insurance companies can act, and should act, for their own benefit, doubtless, but even more definitely to the advantage of medicine, of public health, and of the public. These fields are (a) education in public health, (b) medical supervision of individual policyholders, and (c) standardization of community health activities. Of these, *the latter is wholly new*, while the other two should be done in the future on a scale and in a manner so much more advanced over the present procedures as to make them also new in effect.

New Educational Methods

These three definite steps here proposed for insurance to follow are intimately connected and are all at bottom educational. Education of policy-holders in protecting themselves from disease, in delaying death, is obviously of value to both insurance and policy-holder. But this education, done now by pamphlets, etc.—good, so far as those pamphlets can go—is far better, more directly, more efficiently done by adding *demonstra-*

tion; that is, personal interviews, direct visits and discussion of personal physical troubles; suggesting prevention, and supervising, even conducting, preventive measures; a regular public health campaign brought personally to the policy-holder, by *life insurance itself*.

This program has, it is true, been carried out after a fashion, in the past, more or less, in some places; but I propose that it be done here in Canada, better, more widely, more intensively; and particularly by *demonstrating and teaching health*—in brief, that the new life insurance public health nurse, the new life insurance public health physician, be not reserved to the sick as have been their predecessors heretofore, but should henceforth deal with the well, before they become sick—that the insurance public health nurse, for instance, shall no longer wait for disease to develop before she administers relief, thus reaching merely those policy-holders who are affected by disease; but shall visit regularly *all* policy-holders, *especially the well*, seeking to develop their health. True, the insurance public health nurse cannot cover this great field alone. As an investigator, adviser, and discoverer of early disease tendencies which may later become serious, she is invaluable, just as the cavalry scout is in war. But the insurance public health physician is quite as much needed. It should be his business, like heavy artillery, to detect and destroy the enemy hidden in force, to search out and deal with the more obscure and formidable incipient diseases before the policy-holder himself knows what threatens him—above all, to provide for the treatment, preventive and curative, possible at these early stages, as often it would not be possible later. Such work has been done heretofore on a voluntary, irregular basis, without uniformity. I propose that it be made a definite item in every policy-holders' life.

I propose that every Canadian life policy should contain a requirement that such examinations be made; that all Canadian life insurance companies should themselves provide the examinations, and that all policy-holders be given a financial benefit corresponding to part of the insurance economies thus effected.

Here is still education, not merely in pamphlets, although they are valuable; not only in personal advice, although that is still more useful; but in actual service. Here is public health of the highest type—conserving also that financial prosperity on

which rests the success of public health and yet combining to lessen its costs, and so widen its use by the public.

An Entirely New Step

So far, so good—and already generally conceded. But a wholly new step is needed. Back of the *individual* life, directly dealt with by life insurance, stand the many *community* causes of death and disease. In general these causes of death and disease are really purely community matters; for the *illnesses and deaths of individuals are in most cases dependent on circumstances beyond their immediate personal knowledge, their immediate personal control*. This is peculiarly true of *infection*, and therefore to *infections* are due the vast majority of both deaths and diseases. Only community action, backed by police powers, can control these; but unfortunately, little is at present being done, compared with what might be done, through community action, for their control.

Communities as they are now may or may not adequately protect their citizens against those infections, the great causes of death and disease, just exactly as communities may or may not provide adequate fire protection. Canadian life insurance companies are as vitally interested in prolonging life, in preventing disease, as fire insurance companies are in preventing fires, and should no longer neglect this great field, quite untouched by them as yet.

Actuarial Research

Life insurance should estimate the life and death risks in a given community, investigate the machinery of that community for promoting the one and preventing the other, and demand public health protection in accord with findings thus established—in short, do for public health the inestimable services that fire insurance has done for the prevention of fires, by bringing financial pressure to bear on the development of community public health efforts. No such service is now done for public health by any organization at present, official or otherwise. Yet fire insurance could not operate without this precaution, which life insurance wholly omits! Here again we have education, practical, direct, useful to life insurance itself and to its policy-holders. Here we have a field in which the life insurance company, through its own public health nurses and physicians, not alone may demand but also itself may supply, the protection required by its own—(Continued on Page 755)

The Welfare of Children In An Industrial Community*

Dwight Manufacturing Company, Alabama City, Ala., Accept Responsibility for Preserving Physical Fitness Among the Mill Children

By MARY V. HAMILTON, R.N., ALABAMA CITY, ALA.

CHILDREN cannot be kept physically fit in any community unless they are first made that way, so the Dwight Manufacturing Company begins at the very beginning by trying to give every child its birthright;—that of being well born. We try to get in touch with every pregnant woman in our community. She is instructed as to the hygiene of pregnancy: urinalysis is made about twice each month and medical treatment is given by the physician if indicated. Our mothers are intelligent women, taken as a whole, and wish to do only those things that will promote the well being of the unborn child. We talk to them in groups at social gatherings and try to make them understand that it is not the women in politics, the professional women, the artist, the business woman, nor yet the social leader that is the woman to be honored today, and that future generations will rise up and call blessed—but these women who are giving their all to bring up children that are, and will be 100 per cent morally, spiritually, and physically fit. Mothers doing this are the ones who in the years to come will make the history of the world. For it is still true that, "the hand that rocks the cradle is the hand that rules the world."

Eight years ago the Dwight Manufacturing Company installed as an experiment, the trained nurse who is also a trained social worker. We had read about the little children of the

cotton mill being driven like slaves with none of the pleasures of childhood, and of the rich mill owners who made money at the sacrifice of little lives, and it was with the hope of being able to put some joy into the lives of these little ones that we decided to leave more pleasant and profitable work in the city, and cast our lot in a little cotton mill town. We could hear in imagination the voices of these little children saying, "Come over, and help us." What was our surprise and pleasure when on meeting the agent, superintendent, and foreman of the mill, whom we had pictured as cold, heartless drivers of human beings to find them kind, earnest Christian men who were interested in the welfare of every man, woman, and child on their payroll. We had heard or read so many times

agitation of the mill child and his zest for play was just as keenly developed as that of the average boy or girl.

Shortly after we came to Alabama, the child labor law was changed so that no child under fourteen years of age was allowed to work. To the women of Alabama, we believe, is due to the honor of putting that bill through.

Like everything good we try to do, there is always something still to be done. One of the greatest problems we have is the children of widows who, on being deprived of the income from the child's labor, must themselves go to work, leaving the responsibility of keeping the home, such as cooking, washing, ironing, and tending babies to little girls whose backs soon bend underneath the too-heavy load. If

the state of Alabama could have gone a little farther when she took her children out of the work-shops and mills and could have provided some way of feeding and clothing the widows' children, many of our "little mothers"

Athletic sports are open to all workers. Competitive games contribute largely to the community spirit.

that these children did not even know how to play. What was our surprise on going through the mill to see some of them playing on their jobs. And as we walked through the village and saw the playhouses made out of boxes, and yards laid off with stones, and broken pieces of china making dollies, tea-things, very much as we had done as a child; or to see the boys playing ball, playing circus, or it might be marbles or leap frog, we decided that the im-

would not become old before their time; and our lads would not be running wild without parental restraint, while the mother works in the mill.

Eight years ago the death rate of infants from birth to two years was alarmingly great,—in 1916 it was over 18 per cent. We have splendid physicians who give their best to this work. We found that what defeated the physician at every turn was ignorance and

*Read before the annual conference of Welfare Workers of Alabama, Birmingham, March 19, 1923.

superstition. Way back in the dark ages some one had told their ancestors that night air was "pizen," so as many as six people often slept in one room with even the cracks under the doors

and windows covered to prevent any of the "pizen" night air from coming in. The old "grannies" of the town followed close on the doctors' track, and could in five minutes with her "yarbs and teas" undo what it had taken the doctor two weeks of patient, earnest work to accomplish. One of these women in particular was a nuisance. One of our physicians had a case of a premature baby. We were so interested in seeing the little one developed into a strong, healthy infant. We were devoting as much time to its care and feeding as could be spared from other work. The doctor was very much pleased and thought that with good team work, the family, the nurse and the doctor pulling together, we could save the little one. About the time when we thought we were out of the woods the old "witch doctor" who had been out of town on a visit returned and on learning of the baby, went to offer her wisdom. She immediately decided the baby had "bone hives" and needed to be scarified. She proceeded to carve a cross on its little back, get a few drops of blood in a spoon—she went to the wash bench on the back porch and filled the spoon from a basin of water some one had left standing after bathing their hands for dinner—and poured blood and dirty water down the baby's throat. Consequently we were called that night, and found the baby with a high temperature, and having convulsions. Well, we just sent a message to the dear old lady that if she ever interfered again with any one we had in charge, we would have her arrested and tried for murder. She was not friendly for a time towards the nurse

and her new fangled notions; but now after eight years to think it over, she is the first one in the village when some one is sick to say, "Send for the Nurse."

In 1916 our death rate, as we stated

A typical four room cottage supplied which makes a real home possible at the nominal sum of four dollars rental per month.

before, was over 18 per cent. With the splendid cooperation of the physicians, the mill officials, and the mothers—who though a little slow at first to give up their traditions—have made it possible for us to reduce our death rate year by year until the year 1922 our death rate in the mill village was less than 5 per cent.

Keeping children physically fit, covers every environment, in fact everything that pertains to child life, homes, schools, church organizations and places of amusements. We try even for material. It is surprising

children for physical defects, that 80 per cent were defective. We were furnished a list of the names of all children and what constituted the defect of each child. Going carefully

over the list we found diseased tonsils, adenoids and dental caries made up furnishing the supplies about 75 per cent of our children who were physical defective. Our agent and superintendent put their heads together and offered the county health officer, who was planning an ear, nose and throat clinic for the County of Etowah, the use of our operating room and hospital as a center for the county with the understanding that our "mill" children would have the work done free, the company furnishing the supplies necessary for the operations.

Modern Dental Office

The Dwight Company are never satisfied with half-way measures, so they fitted up a dental office and secured the service of a first class dentist who gives two afternoons each week, the company paying him, and only charging for the material used in fillings, plates, or bridge work—and that being paid a little at a time each pay-day. In cases of children of widows, there is no charge made how many of our people take advantage of the opportunities being offered them to make their children 100 per cent to the good. The dental clinic, if anything, is better attended than the throat clinic. These people have always been hot on the trail of health, yet they sought it in ignorance via the patent medicine route and the conjuring methods of the quack. We believe that now they are awake to what is true and what is false in the

Bath houses of the Dwight Manufacturing Company.

to keep in touch with them all. After several years of hard work along health lines, we were shocked when our public health officer, Dr. Murphree, informed us after examining our thirteen hundred public school

battle of life, and will see to it, that the future generations are born fit. One of the best things The Dwight Company did toward keeping our little ones fit was to fence in about forty acres of—(Continued on Page 750)

Internal Secretion and Physical Efficiency*

Muscular Efficiency Is Directly Related to the Integrity of Certain Endocrine Glands

BY FRANK A. HARTMAN, M.D., PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF BUFFALO, BUFFALO, N. Y.

TOO much is not to be expected of the internal secretions. Many extravagant claims have been made from time to time, and because of the popularity of the subject, much material of doubtful value is being published.

Internal secretions are products of ductless glands. A ductless gland pours its secretion directly into the blood-stream coursing through its tissue. In this way the secretion can be carried to all parts of the body, acting upon various tissues. Some of the ductless glands exercise such a profound influence that their removal produces death in a short time. All of the ductless glands play an important part in the control of the organism.

Indirectly perhaps all of them affect muscular efficiency; but directly, possibly three exercise some function in this respect viz., the pituitary, thyroid, and adrenals.

In some instances the normal action of these glands can only be determined indirectly by studying the results of removal of the gland or by studying the conditions resulting from a gland rendered deficient by disease. This is true of the pituitary.

Unfortunately we know little that is specific concerning the pituitary in relation to physical efficiency. When the activity of this gland is below normal, as in thyroid and adrenal deficiency, there is a loss in physical power. In mild cases physical power may be merely subnormal. If more severe, movements become sluggish and slight exertion causes fatigue. In extreme cases this weakness may become so pronounced that the subject requires support when standing. On the other hand unusual physical strength is sometimes attributed to overcapacity of the pituitary.

We should like to know more concerning the milder forms of underactivity and overactivity of the pituitary, but in this we are hindered by

the difficulty of early identification of the disease.

Judging from the more pronounced cases, a healthy pituitary function seems necessary for normal muscular activity, but we are not justified in positive statement further than this.

We know more concerning the thyroid because of the easier detection of its disease.

In an individual with sluggish nervous and muscular response it is quite possible that the thyroid is at fault and the physician can remedy the condition by the giving of thyroxin or iodine. It has been shown that a lack of iodine in the food is frequently responsible for a reduced thyroid activity. Thus such cases are more plentiful inland away from the sea, the main source of supply of iodine. Thyroid insufficiency in school children has been reduced strikingly in these regions by the feeding of iodine for several days during the spring and fall. Teachers in physical education may be of considerable use in detecting early thyroid deficiency, for muscular weakness is one of the first symptoms. Fatigue develops easily, and frequently the subject becomes unfit for work. It is necessary to point out the extreme of this condition only insofar as it demonstrates the efficacy of treatment. In cretins, individuals who have never possessed a normal thyroid, the whole growth is stunted. Muscular and mental powers are feeble. Feeding of thyroid causes the muscles to harden and agility of movement is developed. In time the individual may become perfectly normal, provided treatment is started early and is maintained.

Emergency Service of Adrenals

Finally we come to the adrenal glands which appear to be most important of all in muscular efficiency.

Removal of both adrenals in animals leads in a relatively short time (except in an occasional rabbit or rat) to a characteristic muscular weakness. An individual affected in this way tires readily on slight exertion

and evinces a growing inclination to avoid physical effort.

Further evidence that the adrenals play some role in muscular activity is found upon microscopic examination of the adrenals after intense prolonged muscular exercise. They present a picture of great overactivity approaching exhaustion. The fat-like bodies (lipoids) which are normally very abundant, are absent or scant in amount.

In addition there seems to be a close relationship between the relative size of the adrenals and muscular development.

Elliott and Tucker found that higher in the scale of animal life the adrenals became relatively larger. Likewise, the musculature is better developed the higher one goes in the scale of life. Moreover, it seems that the adrenals are better developed in animals which are very active. Watson has found that the weight of the adrenals in wild rats is between two and three times greater than in tame rats. The extremely active muscles of the wild animal is compared to those of the tame animal may account for the difference.

What does the adrenal produce which would be of use in muscular activity? Epinephrin, sometimes known by the proprietary name of ardenalin, is the only substance known to be produced by this gland.

Part of the epinephrin is stored in the central portion of the gland to be released in time of emergency. It has been shown that strong stimuli of various sorts will increase the output of epinephrin in normal animals. Painful stimulation, immersion in a cold bath, the excitement produced by shutting off the air to the lungs for forty seconds or less, all cause a very marked increase in the epinephrin poured into the blood stream. Muscular activity will produce a similar increase as we shall show.

If one removes a small ganglion (superior cervical ganglion) which controls some of the nerve fibers to the iris, in a few days, the iris be-

*Address before the American Physical Education Association, Springfield, Mass., April 12, 1923.

comes very sensitive to epinephrin. Under these conditions, if the epinephrin in the blood is increased beyond a certain amount, the sensitized pupil dilates. If the epinephrin is further augmented the pupil enlarges more. Thus the sensitized pupil may be used as a test for increased epinephrin in the blood.

The effect of exercise on the epinephrin output was studied in cats with a sensitized pupil. It was found that from one and one-half to three minutes of vigorous work in a treadmill caused sufficient increase in the epinephrin to dilate the sensitive pupil. In that time the cat had travelled from forty to 180 meters. If the animal worked slowly, it took much longer for the epinephrin increase to appear. This applies in animals starting from a long period of rest. If the animal had been exercised only a short time before and had rested only long enough for the sensitized pupil to return to normal, it seemed to require a shorter period of exercise to cause a detectable increase in epinephrin as indicated by dilatation of the pupil.

As exercise in the treadmill was continued, the epinephrin output became greater and greater until the pupil might become almost maximally dilated. The magnitude of this increased output seemed to depend upon the intensity and duration of the exercise particularly the former as the following illustration shows:

Two cats led around the room at a moderate pace for twenty minutes (544 m.) showed a small increase in epinephrin output; one of these however showed no increase until five hundred meters had been passed. The same cats exercised more vigorously in the treadmill showed an increase in the epinephrin output in three and six minutes respectively.

Following the cessation of vigorous exercise the increased outpouring of epinephrin persists for periods of time ranging from a few minutes to a few hours. It is known that epinephrin increases the rate of metabolism in the body. Therefore the increased discharge of epinephrin into the blood stream following vigorous exercise may aid the body by stimulation of otherwise sluggish tissues. Everyone has experienced the benefit, especially if his occupation is sedentary, of a short period of vigorous exercise. The increased secretion of epinephrin is probably a factor in this improvement. Mild exercise does not produce such marked effects. This may be due to the smaller amount of epinephrin released.

That epinephrin plays an essential part in muscular activity is indicated by certain experiments of ours.

In rare instances we found cats which did not show an increase in epinephrin during their first test in the treadmill. At this time the cats were not able to travel so far as they were when epinephrin was secreted. One cat showed no increase in epinephrin and was able to travel only 741 m., because of the appearance of convulsions. But on the afternoon of the same day, the cat when tried in the treadmill gave a decided increase in the epinephrin output and travelled three times as far. In fact it could have gone farther.

The epinephrin output increased more and more as the work progressed until the stage of marked increase was reached. Spurts of work were attended by sudden increases in the epinephrin output.

We have also been able to show that intramuscular injections of epinephrin enable an animal to work better. This is particularly true if the nerves to the adrenals have been cut so that increased secretion from the glands cannot take place.

Gruber and others pointed out a few years ago that large amounts of epinephrin when injected into a fatigued muscle would cause the disappearance of the fatigue for a time, and a muscle so treated, which had almost ceased to contract, would recover and go on contracting for some time. It was not known, at that time, that epinephrin is increased normally during exercise.

The beneficial effect of epinephrin is produced in two ways: (1) It causes a shifting of the blood from the skin and organs of the abdomen to the muscles by vascular constriction in the former and vascular dilatation in the latter. Thus the oxygen and food supply becomes more plentiful while the waste products can be more readily removed. (2) It benefits the muscle directly in some way not understood (Martin).

Earlier in our discussion we mentioned that an increase in epinephrin could be obtained more easily if the animal had been working a short time before. This suggests that an epinephrin increase may be an important factor in the so-called "warming up" process employed just preceding athletic contests. "Warming up" is particularly useful preceding races and tests of supreme effort. It not only speeds up the circulation but increases the epinephrin output. The latter further increases the circulation to the muscles and delays the

onset of fatigue. The muscles then are ready to work most efficiently and the athlete does his best.

It is also of interest to physical directors that the development of "second wind" is frequently accompanied by a decided increase in epinephrin. Thus an animal may be traveling along at a certain pace. When suddenly he seems to gain renewed energy, and shows a burst of speed which he is able to sustain for some time. Simultaneously there is a great increase in the amount of epinephrin which is being secreted. Knowing the effect of epinephrin on physical efficiency, it is very reasonable to suppose that the increased output of epinephrin aids materially in the production of "second wind."

It has already been mentioned that anything which arouses the major emotions such as pain or asphyxia decidedly increases the epinephrin output. It seems that it is the intense excitement which accomplishes this, because take e. g., partial asphyxia. We have made a practice in our tests of cutting off the air to the lungs for forty seconds by holding a rubber glove tightly against the nose and mouth. If the animal does not become excited during this period, as is occasionally the case, there is no increase in epinephrin.

Again during another test of equal duration, the same animal becomes excited, then the epinephrin output is increased. Therefore it is the excitement and not the lack of oxygen which really stimulates the adrenals.

In exciting games it is quite probable that more epinephrin is secreted than would be in a listless contest. This increase would undoubtedly be a factor in producing greater physical efficiency.

In conclusion we may say that the secretions of the pituitary, thyroid and adrenal are important factors in promoting physical efficiency. But of the three, whether in quiet life or in extreme tests of physical endurance, the adrenal gland appears to be especially fitted to control muscular efficiency.

Dr. Leland E. Cofer Directs Industrial Hygiene

Announcement is made of the appointment of Dr. Leland E. Cofer, New York City, as director of the Division of Industrial Hygiene of the State Department of Labor. Dr. Cofer has been an officer in the United States Public Health Service for more than thirty years.

A Hundred Cardiacs at Work

Adjustment Must Be on the Basis of Temperamental Adaptability As Well As in Keeping With the Energy Quotient of the Patient

BY GERTRUDE R. STEIN, NEW YORK STATE BUREAU OF REHABILITATION, NEW YORK CITY.

TO BE a cardiac has, in the past, meant a life of dependence upon others, a situation brought about by the ignorance of relatives, their sympathetic attitude and willingness to wait on the patient in their belief that he must never again exert himself in any way. The thought of possible employment for the cardiac is only a comparatively new one. Most specialists now agree, however, that the majority of cardiacs are better off at work than when idle, but it is still a question as to how much work they can do and whether they can work continuously. This is no simple problem to solve. There is no trade suitable to every cardiac, nor is there a single scheme of rehabilitation appropriate to every case. The placement of cardiacs in industry is one of the most difficult problems in placement work.

All placement work of cardiacs, to be constructive, must be individual. Wholesale placement has little value. The great difficulty in placement work of the handicapped is that we have practically no theory on which to base our premises. Our work becomes valuable only after years of experience. Perhaps it may be assumed, therefore, that after placing a few more than one hundred cases and following these for less than a year, it is presumption on anyone's part to attempt to discuss the problem. However, what is to be said in this article is based not on theory, but on the actual experience gathered by the New York State Bureau of Rehabilitation and its agents in handling these cases.

It is doubtful whether the regular employment bureaus can successfully place cardiacs. They are too busy with the stress of their work to give the individual attention necessary. Temperamentally, cardiacs differ so greatly from the average client at an employment bureau that unless some one is deeply interested, they are apt to wander around from one job

to another. Experience seems to prove that, even after placement by persons interested in studying the individual and with some knowledge of job opportunities, only about 50 per cent will be steadily employed. Economically, the cost of maintaining these people in idleness when they have potential productive power justifies every expense and effort to find suitable employment.

Cooperative Effort Called For

What is needed is a placement and vocational guidance bureau which will work in close cooperation with the heart specialists of each community. As time goes on, such a

but a cardiac, often more disabled than either, is frequently required to do work far in excess of his strength. Fortunately, physicians and heart specialists now interpret the degree of heart trouble in terms of possible industrial effort and this is of great assistance to the layman in determining what kind of work the person should do. Placement should never be made without knowing in what classification the doctor has placed the patient. The classification according to work capacity or heart function is, from the layman's point of view, more important than the exact diagnosis. These classifications are now commonly used in New York

City, a copy of which can be secured from the Association for the Prevention and Relief of Heart Disease, 370 Seventh Avenue. In several other cities where special heart clinics are in operation, the same or similar classifications are used. The classifications which will be most frequently used in this paper are:

I.—Organic (able to carry on habitual physical activity).

II.—Organic, able to carry on; (A) Slightly diminished physical activity. (B) Greatly diminished physical activity.

III.—Organic (unequal to any physical activity).

Certain Limitations

In working with cardiacs each case must be considered as an individual one. There are, however, certain physical limitations which hamper all cardiacs. Lifting is the main thing to guard against. There are few cardiacs who can stand the work of a longshoreman, a sailor, a driver, a shipping clerk, or a porter. The more unskilled the work is, the more apt it is to be too arduous; the more skilled trades offering the best opportunity of avoiding heavy strains.

Most cardiacs cannot frequently or continuously climb stairs or run er-

Class in dressmaking at the Trade School for Cardiac Children, New York City.

bureau will collect valuable information about successful and unsuccessful attacks on the problem. The workers in such a bureau will be able to give some definite information on the kinds of work certain types of cardiacs can do. It is only by using the most infinite care and the most scientific methods that any results in working with the cardiac can be expected.

Placement work of the cardiac is more difficult than the placement of other disabled people because the disability is not evident. If a man has a leg injury he is not asked to stand all day. If a man has an arm injury he is not called upon to do heavy lifting;

rands without bringing on attacks. Work as a salesman is usually quite unsuitable. The first jobs of most boys necessitate the doing of a great many errands. This is chiefly due to their lack of any special knowledge of a particular form of work and they are consequently required to do general work which would be injurious to a cardiac. For this reason it seems important to give a young cardiac trade or commercial training if he is mentally capable of absorbing it. Many vocational counsellors think it is necessary for the cardiac to take only a seated job. It is true that he is less exposed to the dangers of excessive lifting or climbing in a seated job than in a standing one, but if all employment of cardiacs is limited to seated jobs, the opportunities are very few. Most of the better seated jobs are held by women, and there are only a few processes in which a man can make a living wage which permit him to remain seated most or all of the time. We must always remember we are dealing with human beings, not "cases," and definitely proportionate to the variety of opportunities offered will be the degree of successful rehabilitations. Wherever a man is strong enough

to do a man size job, let us give it to him. There is no advantage, however, in being too optimistic. If a sedentary job is the only job the doctor believes the cardiac can do and not break down under the strain, an effort must be made to find the right sort of seated job for him.

Some doctors recommend outside work for cardiacs. They forget the fact that most outside work is much heavier than inside work. They also forget that the benefits of the air are often counterbalanced by the changes of temperature and the danger of wetting to those who have rheumatic tendencies and are susceptible to colds
